*Photographers' Benevolent Association.*—It is gratifying to learn that the Photographers' Benevolent Association bids fair to be successful. At the last monthly meeting of the society a dozen new members were elected, and the work of the society inaugurated by a grant of money to a sick and needy photographer. Funds seem to be flowing in very satisfactorily, and subscriptions and donations will doubtless be still more plentiful when the society is more widely known and the roll of members become more lengthy. One point in connection with the body deserves particular mention: during the past season the secretary received several applications from employers in different parts of the country for qualified assistants, and was enabled, in some instances, to supply the information asked for, so that there is a likelihood of the society helping the whole, as well as the sick, and becoming, as it were, a sort of medium between those who want assistance and those who can give it. This will be a very useful feature of the institution if it be properly cultivated.

### GERMAN CORRESPONDENCE.

#### LANDSCAPE PHOTOGRAPHY—THE EFFECT OF PERSPECTIVE. BY DR. H. VOGEL.

I AM out of town, at a watering place, in order to wash off for once the dust of the city in the briny waves of the Baltic. It was my intention to do nothing—absolutely nothing; but I could not resist the temptation to take along some photographic apparatus. I believe photographers are like actors: after one has worn out a pair of shoes on the stage he cannot leave it: and after a photographer has used up a pound of nitrate of silver he is wedded to the dark chamber for life. The amateur is almost in a still worse condition. Many a pretty study excites me to work, for the coast here is highly romantic. Mighty dark cliffs, similar to the Shakspeare Cliff at Dover, rise here out of the water, the summits crowned with the primeval forest of the finest beech and

oak. Deep gorges intersect the rocks, mountain torrents rush down towards the sea, and immense boulders cover the beach. Further inland you meet with curiously-formed giant tombs, with numerous remnants of flint implements and weapons peculiarly formed, fortifications, and heathen altars, all relics of a people long ago passed away, and of whom we only know by legends. Unfortunately the intrusive element, in the shape of farmers' boys and servant girls, interferes with taking the picture of these remnants of the remote past, for these people believe that I am an itinerant photographer, and ask me regularly how much I charge for half a dozen cards. Wind and weather also interfere very frequently: but seldom are the leaves quiet, and still more rarely am I favoured by a ray of sunlight which brings light and shade into the landscape. Here is abundance of splendid material for such show pictures as have been made by Breese in England. I mean his splendid instantaneous photographs, where surging waves and overhanging clouds are illuminated by a sudden burst of sunshine—pictures that are made daily at the Falls of Niagara, but which succeed so rarely in the less favourable atmosphere of Germany. Unfortunately we do not meet with these pictures any longer in the shops, for Breese is reported dead, and his successor has not been found yet, although the beautiful transparencies were readily bought, in spite of their high price. It is, anyway, peculiar that the artistic landscape photographers do not succeed on the Continent. Such magnificent pictures as are made by Robinson and Cherrill we look for in vain in Germany, and it is significant enough that English photographers make our own a rather strong competition in the landscape line.

It seems that generally the photographer is satisfied with taking the view that most people call for, but he does not care how the illumination is, or if the light comes from the front, from behind, or sideways. The travelling photographer is satisfied to make in the shortest time as many pictures as possible, and to travel through the country as quickly as possible. Under these circumstances, to wait for the finest effects of light and shade is out of the question.

This evil is mainly due to the public itself. It makes great pretensions when its own dear self is concerned. When a portrait is wanted, vanity comes into play; but with landscapes the case is entirely different. If only the outlines of the favourite spot are recognized, the public is satisfied, and does not ask whether the plate is over or under exposed, whether it is spotted or streaked—in fact, it accepts the meanest kind of work, provided it is cheap; and the best photographer, who would like to make the best kind of work, finds to his regret how little even educated people know to value his talents. Such indolence cannot, of course, promote progress.

There are very clever landscape photographers, particularly in the Alps. I refer, for instance, to Baldi and Wurthole in Salzburg, Johannes in Portenkirchen, and Lotze in Bozen. In North Germany we had formerly artists of equal reputation, but it seems that they have lately turned their attention to other branches of photography. We must not forget that the Alps furnish the photographer with a much richer material than the flat plains of North Germany. In the Alps we can turn the camera in whatever direction we choose, and we will, almost in every instance, find a good subject. But it is different in a level country. Here it becomes difficult to fill out the picture. We find, for instance, a charming village surrounded by trees and woodland. We direct the camera towards it, and we get a picture. But how does it look? The village with the surrounding forest occupies a small strip in the centre of the picture; above it there is a wide blank space representing the sky, and below a broad space of tedious foreground in the shape of a large stubble field.

These drawbacks may be remedied by a lens with a long focus. Sky and foreground appear smaller, and the centre larger; but, unfortunately, the angle of view will decrease with a longer focus, and many a landscape which stretches

over a considerable horizontal surface cannot be taken with a long-focussed lens. It becomes, therefore, necessary to stick to a short-focussed lens, and thus it happens that we see many a marine view in which the tedious sky and the equally tedious foreground drive the artistic viewer to desperation. The painter easily circumvents these difficulties. He fills the sky with handsome clouds, lets the sun burst through them and throw wonderful reflexes on water and foreground, and brings in this manner harmony and poetry into a landscape where photographers despair on account of the monotony of the subject. Yes, the painters nowadays give a preference to the level country, where sky and foreground leave a clear field for the display of their fancies; while in mountainous regions like the Alps, the mountains themselves fill the picture from bottom to top.

In view of these miseries of the landscape photographer, it is really enjoyable to record some new conquest in the realm of geographical photography. These are the pictures from the desert expedition by Gerhard Rolf, taken by Ph. Remelé. Rolf's expedition was organized by the Viceroy of Egypt, and entered the sandy waste of the desert for the purpose of tracing the roads of the caravans, the oases, the geological formations, &c. Zoologist, botanist, astronomers, and mineralogist accompanied the expedition. It is the first African one which was accompanied by a photographer. The oases "Charzeh" and "Tarafre" were reached, and strange rocky landscapes and interesting ruins of ancient Egyptian temples were discovered, and an abundance of the most curious views were taken, until the further progress of the enterprise was stopped by an endless chain of sandhills. Of all these strange objects Remelé has made splendid pictures, which together form an album of about eighty pictures. The Viceroy has ordered hundreds of these to be made at his own expense, and intends to present them to prominent learned institutions.

Lately I made an observation on the peculiar effect of perspective in photography. A sculptor constructed a splendid monument—a kind of mausoleum. The same presented a cubical base, surmounted by a cupola. The plaster model of the building was about three feet high. The building itself would reach a height of sixty feet. To show his work, the sculptor ordered a photograph to be made of the model, if possible with landscape surroundings. After much trouble, the photographer fulfilled all these conditions. He placed the model in front of a landscape background, on an artificial hill, in which pots with cypress and myrtle were buried. A plate of sixteen inches was made from this model. Everything succeeded, and the photographer was satisfied with his work, and others who saw it praised it highly. The picture was handed to the sculptor, but he was by no means delighted. He did not say a word, paid the bill, and left. He took it to the Artists' Society, and demonstrated to his colleagues that photography is utterly unable to make a correct picture of anything. We experience here quite often that artists take a delight in taking hold of inferior pictures, and to demonstrate from them the incapacity of photography.

The mausoleum mentioned above made, indeed, a rather peculiar impression, which was felt by persons who did not understand anything about art. The landscape looked quite natural, but the building unnatural, although very few could explain why. The reason of this lay in the perspective proportions. If we take a photograph of a cube one foot high, and place the objective on a level with the cube, the edges will separate but little. If, on the other hand, we photograph a cubical building which is sixty feet high, and place the camera at the foot of the building, then the lines of the cornices will very considerably tumble, as the artists call it, and the higher the building is the more marked will this appear. The lines of the cornice did not fall sufficiently, and did not give the same impression a high building would make. The question arises, could this be avoided? At first sight this seems impossible. And still it can be done. If we photograph a cube, and place the objective at various

distances from the camera, we will find that the lines tumble more and more the closer we get to the cube. Such an approach is possible with a correct working wide-angle lens—as, for instance, the Zentmayer. Such leuses have sufficient depth, and make it possible to work at very short distances. If such an instrument had been employed in this instance, a splendid picture of the model would have been the result, which, also, would have made the impression of a large building. We often complain of the exaggerated perspective of wide-angle lenses: in this instance it would have been no disadvantage.—*Philadelphia Photographer.*

#### A FEW WORDS ON THE BEER AND ALBUMEN PROCESS.

BY J. M. TURNBULL.\*

As I have had a good deal of experience this summer with this process and modifications of it, I may be allowed to give my opinion of it, and also a short account of a set of experiments I have lately tried with the different forms of it, in order to find out which is the best and most sensitive. Mr. Davies, in a paper which he read before the June meeting of this society (and from which I have taken my title), recommends the addition of more silver and pyrogallic acid to the beer and albumen. He says:—"If additional rapidity is needed, it is conferred by increasing the proportions of free silver and gallic or pyrogallic acid, and cautiously reducing the strength of the beer-albumen with distilled water." As some plates which were prepared in the beginning of the summer without the addition of either pyrogallic acid or silver were very sensitive, I felt very much inclined to doubt that this was the most rapid form of the beer and albumen process. I resolved to try this form of it against plates prepared with the omission of both silver and pyrogallic acid, and also Captain Abney's form of it, as given in the PHOTOGRAPHIC NEWS ALMANAC for this year. With regard to Mr. Davies' addition of silver to the beer, I had serious doubts of there really being any free silver in the preservative, as poured upon the plate, at all. Mr. Davies recommends the addition of one grain of silver to one ounce of beer. Now, I should think that there was enough of chlorides and organic matter in an ounce of strong sweet ale to reduce entirely the one grain of silver, and that should, by any chance, free silver be left in the beer, it would entirely be reduced on the addition of the pyrogallic acid and albumen, which would form some complex organic salts of silver. In my own trials of it I used two grains of silver to one ounce of beer. After adding the pyrogallic acid and albumen, some of the preservative was poured into a test tube, and a chloride added. I made several trials, but I really could not say that I detected free silver. I feel, however, that I should leave this an open question, as the colour of the beer—or, rather, the strong sweet ale—was rather high, which prevented the chloride of silver, if any was present, from being seen.

With regard to the addition of pyrogallic acid to the preservative, I have never before heard of it in connection with any dry process as a sensitive agent. Either it or gallic acid has been used in connection with the albumen process as a preservative, a final wash of any of them being said to confer great keeping qualities on the plates—my opinion of it, in connection with the beer and albumen process, being, that it has no sensitizing properties at all, and that it only acts as a preservative, and that unless the plates are intended to be kept a very long time, it had better be omitted from this process altogether.

With regard to the modification of the process as proposed by Captain Abney, I cannot say that I regard it as an improvement, but rather the reverse, as I can only look on it as a complication of what is in reality a very simple

matter.\* As worked by Mr. Davies, the preservative is applied at one application; but as proposed by Captain Abney, you have two preservatives, with a washing between. I therefore prefer Mr. Davies' plan as at once the simplest and best. There is little other difference, as both use the same materials, with the exception of the ammonia proposed by Captain Abney. Let us now shortly enquire of what possible use ammonia can be as employed with albumen and beer. Captain Abney says nothing in his article to the YEAR-BOOK of its use, but in a letter to the journals, the week after the publication of Mr. Davies' paper, he says, "I lay great stress on rendering the film alkaline; it is an important means for securing rapidity." (See PHOTOGRAPHIC NEWS, June 19th.) That the Captain is mistaken in this I will shortly show. In the meantime, let us enquire about the use of the ammonia. The Captain says: "To each white (of egg) one fluid drachm of ammonia must have been added." Now, if we add one drachm of ammonia to one ounce of albumen, the result is merely a mechanical mixture of the two. There is no acid to neutralize in albumen, and there can be very little, if any at all, in the film, after the free silver is washed off, at any rate; if there is any left, it has no effect whatever on the sensitiveness of the film, as my comparative trials with other plates showed. I therefore regard the addition of ammonia to the albumen and beer as simply useless, and only tending to complicate the process. The application of the mixed albumen and beer may therefore here be dispensed with, and also the separate washing, and the preservative applied as in Mr. Davies' method, which will at least save a great deal of time in the preparation of the plates. I may just as well say here, that instead of Captain Abney's method being more rapid, as he seems to think, it is actually slower than either Davies' method with the silver in the beer, or the other method without the silver and pyrogallic acid.

I will now shortly detail the experiments I made with the different plates. My first trials were between Davies' method, with the silver and pyro, and the other method, with only the plain beer and albumen. Plates were prepared in every way the same, the only difference being that the preservative in the one had two grains of silver to the ounce and one grain of pyrogallic acid, while the other was only the plain beer and albumen. The plates were exposed at the same time, on the same subject, and got precisely the same exposure, the light being very steady. I purposely under-exposed the plates, to see what difference there would be in the development. On developing them, the plate with the silver and pyro began to show slight traces of an image first; but the race is not always to the swift. After a while it began to lag, and the one with the plain beer to have the advantage. In the end both plates came up well, though both were under-exposed, and required a little forcing, the one without the silver being the best and most brilliant negative of the two, the other being flat and slightly fogged in comparison with the other; the one without silver being quite as well exposed as the other.

Another trial I had was with plates prepared with the same collodion and bath, the beer and albumen being also the same, but made up in the different proportions used by Mr. Davies and Captain Abney; and also the method without the silver and pyro. The plates were exposed one after the other on the same subject, without shifting the camera. They got exactly the same exposure; this time a full exposure was given. To give the plates equal justice in development, they were placed all three together in a flat tray. The preservative having been washed off, a three-grain solution of plain pyrogallic acid was poured over them all. In a short time a very faint trace of an image began to show on the plate by Davies' method, and

\* As Captain Abney's silence in relation to the questions raised may be misunderstood, it should be stated that he is at the present moment in Alexandria, or on his way thither, and will not return until after the transit of Venus in December.—Ed. P. N.

\* Read before the Edinburgh Photographic Society.

also the one with the plain beer, while Captain Abney's as yet showed nothing. I then added a few drops of ammonia, when the whole three began to come fully out, the plain beer leading, if anything.

With all my experience in photography, both wet and dry, I could not help a smile rising to my face as I thus held the dish in my hand, and waited to watch the race for first being developed, and thought of the plates being labelled on the back, "Davies," "Abney," and "Plain Beer;" and could not help exclaiming to myself, "May the best man win."

The plates being fully out, they were intensified with a little acid pyro and silver. The conclusion that I came to with regard to rapidity was, that the plate by Davies' method and the one with the plain beer were as near as possible equal, neither having the advantage, both being fully exposed; while the one by Captain Abney's method would have required a little more exposure to have made them equal. From Captain Abney's letter already spoken of, he seems to be under the impression that plates by Davies' method cannot well be developed by the alkaline method. Such is not the case, as plates by Davies' method have been developed with the alkaline development ever since it has been introduced. I have myself developed plates by this process with as strong an alkaline developer as it is possible to use.

I will now sum up by stating what I think is the best form, and also the simplest, of the beer and albumen process, and that is the keeping out of all silver, pyrogallie acid, and ammonia from the preservative, and using only the simplest mixture of plain beer and albumen, unless when the plates are required for very long keeping, then the one grain of pyrogallie acid to the ounce of beer should be added, when that would give what I am almost tempted to call indifferent keeping qualities. If additional rapidity is to be got by this process, I should think it would be in the direction of diluting the mixture of beer and albumen—to what extent I cannot at present say; but I should think to the extent of equal parts of water, or even double or treble that quantity. Any further experiments I make will be in this direction.

Having now spoken of the preparation of the plates, I need say nothing of their development, but would simply recommend anyone trying the process to follow the directions of Mr. Davies and Captain Abney, both of these gentlemen having stated them so clearly and ably that I need not add one word.

In conclusion, I would just say that I can endorse all that both of these gentlemen have claimed for the process, and that it is one of the best, if not the very best and simplest dry process which we at present have; and if I have contributed to simplify it still further, my object will have been fulfilled.

### SPIRIT OF THE JOURNALS.

BY W. H. DAVIES.\*

WELL, the title seems an odd one, seeing that it is four months ago since the first of this projected series of papers was brought before the society, and that business avocations have prevented me from being present at a single one of the out-door meetings held since then. By-the-bye, I had forgot that memorable one where our worthy secretary's traps were subjected to the intelligent scrutiny of Lady Ruthven's milk cows, who, while the photographers were having luncheon with her ladyship, proceeded to swallow the rather indigestible matter of which cameras, and tripod stands, and double dark slides, and focussing cloths, and other impedimenta belonging to the out-door section of the E. P. S. was composed.

In like manner I have set myself to swallow and, if possible, digest the rather indigestible contents of the papers; and, accordingly, having made the preliminary

number of wry faces, I begin, but always premising that the last four months' journals are to me a sealed book, and that I intend to look back for a month only, and that the notes will be at least as fresh, if not fresher, to me than they are to you.

First in order we may note the proposed exhibition of the Bengal Photographic Society, which seems one of those showing a large amount of healthy vitality. I might suggest an amendment of the seventh rule: "Exhibitors must make their own arrangements for the removal of their photographs the day after the closing of the exhibition." Now, I apprehend that few British photographers have East India agents, and the removal, or packing and returning, of the pictures should have been undertaken (for a fee, of course) by the society for all foreign exhibitors.

The letters from correspondents often contain about the most interesting matter in the journals, and much good frequently results from them. In the News, Sept. 11th, Mr. Houlson asks how to mount photographs on thin boards so that they may not cockle after mounting, and as I do not see that he has been answered, I will try to help him and others who may be in the same predicament. The way to do it is this:—Take a sheet of stout printing or cartridge paper, damp it thoroughly all over, then take as many photographs (untrimmed) as will cover it, damp them also, then paste them down, with starch paste, on the cartridge paper while both are quite damp, pressing out all air bubbles, and removing any little knobs of starch, &c. Then glue all the edges of the sheet of cartridge paper, keeping clear of the photographs. Attach this to a drawing or straining board, and stretch the paper with the prints as neat, tight, and flat as possible, and put it aside to dry. When dry, cut the paper off the board, and trim the prints; they will then be quite flat, and need no pressing. Neatly attach them to the thin boards, stout paper, or serap book, by gluing about one-eighth of an inch all round and attaching the two together. This will give a beautifully flat mounting, with no cockling. On no account are prints, after being treated as described, to be pasted all over the back, as that would simply undo what has been done. I trust this will prove a bit of wholesome advice to more than Mr. Houlson.

The oasis in the desert is not more pleasant to the weary traveller than the letter of my friend, Mr. Joseph Collier, from the slopes of the Sierra Nevada, part of which appears in this month's *British Journal*, was to me—coming, as it did, in the midst of a weary wading through the *Journal* in search of something to fill this paper. With what zest and gusto the great pawky Scotchman goes into his romantic expedition, and improvises the necessary means to get over difficulties. All of you should study this delightful letter. Whatever may be the pecuniary results of the adventure, it will at least make Mr. Collier's burden no heavier to know that I and all the rest of his Edinburgh friends wish him God-speed and the best of luck in the new home he has chosen.

The chapters in the *British Journal* on the saving of waste should be carefully studied by professional photographers, containing, as they do, the long-acquired experience of Mr. Foxlee, than whom there are few more competent to teach. On one point only do I join issue with him: it is as to the saving and throwing down of hypo wastes. The plan which I have had in operation for years is, I think, a better one than that proposed by him, and is very simple in working. A wooden tank, lined like a cistern with pretty thick zinc, such as is used for baths, is provided, and is placed outside the developing room. The developing sink, which is a large wooden one, has three exits: one for the waste water, communicating with the drains; one for hypo, communicating with the zinc-lined cistern (which last, I may mention, has a tap for running off the exhausted hypo above two-thirds of its height); the third exit leads to another wooden tank, which is provided for the reeep-

\* Read before the Edinburgh Photographic Society.

tion of the wastes from developing plates, washing prints, dishes, &c., which are all run into the same receptacle, which is under the developing sink. A couple of common vulcanized balls are used as stoppers for either of the two exit pipes which are not in use. A supply of salt is added from time to time, and the surplus water run off as it accumulates.

When sufficient of the chloride and other wastes have been thrown down, it is collected, and fused along with the deposit recovered from the hypo tank, which last is now and again agitated, and the sides of tank scrubbed to keep the exposed surface of the zinc in good working condition.

I have found this to be a very efficient and easy plan to recover the hypo wastes, involving no trouble, and never getting out of order. The present arrangement has worked for ten years without repair, which I think is proof positive of its lasting qualities, as well as of its efficiency.

Among the foreign notes in the *British Journal* for September 18 is one from Dr. Vogel on intensifying with permanganate of potash, with which he seems to be charmed.\* Being, as I presume it is, his first experience with it, I have no doubt he believed he had discovered a good thing. But appearances are deceptive. The learned doctor will find, as I have, and as Mr. Jabez Hughes did, and published his experiences thereon years ago, that it is one of the least permanent of all the methods of intensifying. If the learned doctor can discover an intensifier as easily applied, as effective for the time being, and permanent, he will confer no small boon on photographers; but this is not one.

Very pleasant is the irony of Scott in the *British Journal*, who dates from the unpronounceable "Pass of Queghanhulich;" and we wait with impatience for a treatise on the qualities, styles, and prices of the clothes which "clothe the spirits." I trust he will add a word or two on their wearing qualities, and ascertain, if he can, whether we are to meet our lost ones in the spirit land as the wrinkled and toothless grannies and grandfathers who sometimes die here, or rather, as we love to think of them, in the heyday of their youth, and strength, and beauty. Do, good Scotticus, be speedy with your report, for we are all waiting for the next advent of so excellent a reporter.

I may here conclude this month's hasty notes by signifying that I have tried to avoid subjects likely to be taken up by the monthly summary of the NEWS, the gossip monthly notes of the Peripatetic, as well as the occasional notes from the North of our esteemed hon. secretary, Dr. Nicol; and rather choosing points which might be overlooked, or such as are of practical utility, or where a bit of practical advice may be of use; and I trust that whoever takes it up next may adopt their own, and not my way, and thus we shall have new, original, or at least varied, ways of seeing things brought before us every month.

#### ON MEASURING THE INTENSITY OF LIGHT.

In the *Annalen der Chemie*, M. Marchand gives an account of some experiments undertaken to estimate the intensity of chemical rays. When oxalate of iron in solution is exposed to light, carbonic acid is developed, and from the amount of gas set free some opinion may be formed of the chemical intensity of the light that has acted upon the compound. Unfortunately, the iron remaining behind adheres to the sides of the glass in an insoluble form, and thereby prevents the further penetration of the rays. For this reason M. Marchand makes use of a solution of chloride of iron, and a solution of oxalic acid, which are likewise decomposed by light with development of carbonic acid.

One equivalent of oxalic acid and one of chloride of

iron are employed for the purpose. To produce a sensitive liquid, fifty grammes of chemically pure oxalic acid are taken and dissolved in water saturated with carbonic acid, and diluted to the extent of a litre. The chloride of iron must be quite pure. It is produced by conducting chlorine gas through subchloride of iron (produced by dissolving iron in hydrochloric acid) until no more is absorbed, and the superfluous chlorine is thrown off by means of a current of air, but without boiling. The fluid is then diluted to the specific gravity 1.2, and then carbonic acid is introduced until the fluid is saturated therewith. These liquids are kept ready for use.

For conducting the experiment, ten cubic centimetres of chloride of iron are mixed with twenty cubic centimetres of oxalic acid solution, and these are put into a flask filled with carbonic acid water. The flask is in connection with a graduated tube, in which the gas is developed on exposure of the mixture to light, the carbonic acid being collected and measured over glycerine.

The saturation of the different fluids with carbonic acid is necessary, as otherwise they would retain any gas developed by the action of light. Of course, by an elevation of temperature, or diminution in the air pressure, some of the carbonic acid is lost. But this does not in any way impair the accuracy of the apparatus, according to M. Marchand, although Dr. Vogel, of Berlin, has his doubts on the matter.

The amount of solution gives off in the daylight about 260 cubic centimetres of gas, and then the reaction ceases, although, according to theory, as much as 340 cubic centimetres are contained in the liquid. For this reason fresh solution is made use of as soon as 260 cub. cents. of gas have been set free.

An apparatus of this kind has been in action ever since 1869. M. Marchand has tested it with the spectrum, and found that the strongest action is between F and G, stronger even than close to G; different, therefore, as Dr. Vogel points out, to the behaviour of photographic films.

M. Marchand has calculated the average amount of carbonic acid set free daily in his instrument, and he sets down the quantities during the different months as follows:—

January ... ..	1.84 cubic centimetres
February ... ..	3.93 "
March ... ..	6.441 "
April ... ..	14.095 "
May ... ..	19.459 "
June ... ..	21.043 "
July ... ..	21.410 "
August ... ..	18.917 "
September ... ..	13.649 "
October ... ..	6.858 "
November ... ..	2.885 "
December ... ..	1.795 "

Thus the chemical intensity of a June day is nearly twelve times that of an average day in December, and photographers cannot expect, therefore, to do more than a twelfth of the work as regards printing, &c. It is to be hoped that some simplification of Marchand's apparatus may be devised for practical purposes.

**BLISTERS.**—Blisters, O blisters! how can you bother me so? What a nuisance! Prints all mottled, and disgusting to look at. What shall we do? All sorts of prescriptions have been tried, and when one is found effective the tone is spoiled, and disaster is the consequence. There is a 'cat in the meal-bag' somewhere, and we must get her out. This much for the wrinkle; now for the dodge. After the prints have been toned and well washed, immerse them in a strong solution of alum, where they should remain about two minutes. Then remove them to fresh water, and wash out all traces of the alum, after which they are ready for the fixing bath. Moral:—Carry the prints back to clean water, after having passed them through any solution used in toning, before passing them into another solution.—I. B. WEBSTER in *Philadelphia Photographer*.

\* The first publication of the use of permanganate of potash as an intensifier was made in the NEWS some years ago, and consisted in the detail of some experiments of our own. We have not found any lack of permanency in such negatives.—ED. PHOTO. NEWS.

## THE PHOTOGRAPHIC EXHIBITION.

THE exhibition of the Photographic Society opened with a conversazione in the rooms of the Society of British Artists, Suffolk Street, Pall Mall, on the evening of Tuesday, the 13th instant. A tolerably large assemblage of visitors examined the pictures with much interest and satisfaction; but the attendance was scarcely so numerous as on former occasions. Very considerably varying opinions were expressed as to the relative excellence of the exhibition, the preponderating impression—probably nearest the truth—being to the effect that, with much individual excellence, the general quality of the display was inferior to that of last year. The number of contributions this year is somewhat smaller than last year, and the number of contributors is considerably smaller than last year, ninety-one persons having sent in specimens this year, as against one hundred and twenty-nine last year. We find some new contributors, and welcome back some who have not contributed for many years; but we have, on the other hand, to regret that several whose works have been distinguished ornaments on former occasions are conspicuous by their absence now. Captain Abney is entirely unrepresented. Mr. Robinson, who has not omitted to contribute for fifteen years past, with the exception of the pictures sent to the Crawshay competition, is unrepresented. Mr. Earl, whose noble landscapes have always been so welcome, is unrepresented. We miss with regret examples of the work of Manners Gordon, Henry Cooper, Frank Good, William Mayland, Marshall Wane, T. M. Brownrigg, Fritz Luckhardt, C. Reutlinger, C. Bergamasco, J. Albert, M. Denier, Professor Koller, and others whose exceptionally fine work added so much to the interest of the last exhibition.

On the other hand, there is much room for congratulation as to the excellence of much of the work in the present exhibition, and the progress illustrated in various directions. The magnificent specimens sent in by Messrs. Spencer, Sawyer, and Bird, illustrating progress in three distinct directions, would alone form an admirable display. These pictures, the majority of them of enormously large size, illustrate the especial phases of progress in photography during late years: they are examples of one of the most perfect modes of enlargement yet brought under the attention of photographers; they are examples of carbon printing of a degree of excellence which seems to leave nothing to desire; and they include examples of photo-mechanical printing unusually fine in every way. In

photo-mechanical printing, the Woodbury Printing Company send work which cannot be excelled, the texture and whole quality of the prints being of a character which requires very close examination to distinguish between them and ordinary albumenized silver prints. In the hasty examination possible during a conversazione (no private view having been available this year) it is difficult to make precise or detailed observation of the various contributions, and we can here only give first impressions of a few of the most prominent pictures. In portraiture, Mr. Valentine Blanchard remains *facile princeps*, and he has, we think, in some qualities exceeded his former work. His portrait of Barry Sullivan, the eminent tragedian, is a singularly noble piece of work, both as picture and portrait, as are also the portrait of Mr. Manville Fenn and that of Mr. Dillon Croker. Some portrait studies in character, and two Oriental interiors with portraits, are also very admirable. Mr. Abel Lewis, of Douglas, exhibits some very charming examples of portraits, delicate, chaste, and artistic. Mr. J. M. Young, of Llandudno, has some exceedingly capital work. One, entitled "The Bouquet," a portrait of a lady, is not exceeded by anything in the room; the treatment of the drapery and background, modifying the light and shade in printing, are managed with rare artistic taste. A portrait of a little boy, by Herr Hugo Theile, of Dresden, is very fine, and if a little of the interior had been sacrificed, would have been perfect. It has now, unfortunately, somewhat the appearance of a view of an interior with a little boy in the centre. The one portrait\* contributed by Mr. Slingsby is as perfect a direct life-size head as we have seen: massive, yet delicate, and perfectly modelled. Mr. Crawshay has some very capital work, both life-size and smaller. Mr. Rejlander sends two or three noble portraits. Amongst the portraiture which was deserving of special attention we may mention the work of Mr. Boucher, L. Bertin, and M. Lombardi, all of Brighton. Mr. W. Gillard, Mr. A. W. Wilson, Messrs. Bary and Co., J. E. Mayall, Vandyke and Brown, G. Hooper, Mrs. Cameron, R. F. Barnes, also send very fine examples of portraiture.

There are not many *genre* photographs or pictures which should be classed rather as artistic studies than portraits; but assuredly the fine frame of examples of child portraiture exhibited by Mr. Faulkner is full of artistic gems, and will repay long study. It may add to the interest in the eyes of many readers if we point out that the wonderful delicacy and richness of the prints, as prints, is due to the use of the collodio-chloride process in printing. The same remark may be made of the subject pictures by Mr. Bruce, of Dunse, which are singularly fine in every way. Mr. A. Ford Smith has one or two good bits of *genre*. Mr. Werge has a number of very admirable studies of children, draped and undraped, many of which are exceedingly fine. Mr. H. G. Cocking has some good subjects, well treated. Mrs. Cameron sends some of her characteristic pictures, many of them with much undeniable artistic quality, but also lacking much which, without derogating from their artistic quality, they might have possessed, of photographic excellence. The Misses Davison rarely fail to send some portrait studies with fine artistic feeling, nor have they on this occasion. Messrs. Jabez and Alfred Hughes send a variety of fine subjects, especially notable as perfect examples of collodion transfer work, as well as fine pictures.

To the landscape work we can barely make reference now beyond remarking that there are many very fine examples, the names of Bedford, Col. Wortley, Beasley, Bool, Col. Roche, Hudson, Col. Dixon, and other well-known photographers, affording guarantee that in this department the exhibition will contain worthy work.

\* We refer to the contributions to the Crawshay Competition in a separate column.—F.D.

## THE CRAWSHAY COMPETITION.

The pictures competing for the prizes so liberally offered by Mr. Crawshay, of Cyfarthfa Castle, are hung in two separate rooms, forming part of the exhibition of the Photographic Society now open in the Suffolk Street Gallery, the figure subjects in one room and the landscapes in another. In the former department the competition was not larger than last year, but in the landscape department the contributors were numerous. The prizes were awarded as follows.

The first prize, for the three best life-size heads, £50, Messrs. Chaffin and Sous, of Yeovil.

For the second best three of the same size, £25, Mr. Crawshay's three contributions received the award; but an intimation having been received to the effect that in case of any award being made to the pictures contributed by Mr. Crawshay himself, he desired the prize to be passed on to the next in excellence, it was awarded to Messrs. Robinson and Cherrill.

For the three best heads on 15 by 12 plates, 4½ inch faces, £25, Messrs. Robinson and Cherrill.

For the three second best of the same size, Mr. R. Slingsby, of Lincoln.

For the best enlargement on a plate 20 by 16, C. Ferranti.

It is noteworthy that amongst the competing pictures for the prizes for large heads were several which were altogether untouched. Those of Messrs. Robinson and Cherrill, which received the second prize, were of this character, as were those contributed by Mr. Neilson, of Edinburgh, most noble work, and much commended by the judges. The competition for the enlargements was very close, as all the contributions were excellent. The enlargements of Mr. Edwards were exceedingly fine. Some collodion prints on opal glass, by Vandyke and Brown, were much admired. A collodion transfer, by Mr. J. E. Palmer, was very fine. A head by Mr. Gillard, which arrived too late for competition, had many fine qualities, although too much out of focus in parts. Some enlargements by the Woodbury Printing Company had fine qualities, being very delicate, but a little grey and somewhat flat.

In the landscape competition, the first prize was the three best landscapes of any size not less than 10 by 8, £25, Messrs. Robinson and Cherrill.

For the second best three of the same size, £12, Mr. W. D. Sanderson.

For the best landscape of any size, £10, Messrs. Robinson and Cherrill.

For the second best landscape of any size, £5, Mr. W. D. Sanderson.

A number of the competing landscapes were especially approved by the judges, amongst which we may mention those of Messrs. A. and J. Bool as having more than once entered into the voting.

The judges were the same gentlemen as officiated last year: Dr. Diamond, Messrs. J. Glaisher, Leslie, G. Wharton Simpson, W. Mayland, and H. Baden Pritchard.

## VIENNA PHOTOGRAPHIC EXHIBITION.

We have to announce that an exhibition of photographs will be held in Vienna next year, under the auspices of the Vienna Photographic Society, of which the well-known portraitist, Herr Fritz Luckhardt, is secretary. There is some talk of Herr Luckhardt paying a visit to this country during the present year, to assure himself personally of the status of the art in Great Britain; and in the event of his doing so we shall be able to obtain from him personally more definite information on the subject than has hitherto been promulgated. It will be seen, however, from the notice we append—which is all the information that has yet been made public—that it is intended to keep the exhibition

open for a couple of months only, although the term may subsequently be extended, if such a course is found to be desirable. There is no mention of any medals or awards being made to exhibitors, but we believe the Voigtlander medals—of which eight or ten have been offered for various productions and processes—will be adjudged on the occasion. The following is the official announcement made by the Vienna Society in their organ, the *Photographische Correspondenz*:—

"It gives us particular pleasure to be able to inform our readers that the Photographic Society of Vienna is enabled, through the liberality of the direction of the Imperial Museum for Arts and Industry, to establish an International Exhibition of Photographs in the above named museum. The same will be opened in the middle of April, 1875, and last at least until the end of May. Further particulars will be shortly published. In the meantime, letters and enquiries should be addressed to the Council of the Vienna Photographic Society, III. Hauptstrasse 9, Vienna."

## FRENCH CORRESPONDENCE.

DU COS DU HAURON'S HELIOCHROMIC PROCESS: MODIFICATIONS—METHOD OF TRANSFERRING AND MOUNTING THE MONOCHROME PRINTS—THE STORY OF THE BURNING OF THE PARIS DIORAMA, AND NARROW ESCAPE OF DA GUERRE'S INVENTION.

SOME months ago I gave an account of the modifications recently made by M. Ducos du Hauron to his method of obtaining photographs in colours by the aid of three monochrome clichés. It will be remembered, no doubt, that, profiting by the experiments recently made known by Dr. Vogel, of Berlin, M. Ducos has lately employed, with advantage, coralline in his collodion, and in his last communication he tells us that in this way, and by using a second silver bath, he is enabled to work with much greater rapidity. This second bath is but a one or two per cent. solution of nitrate of silver, and the author thus explains the nature of the acceleration produced.

In proceeding to obtain his negatives on his original plan, the production of the clichés, he found, often necessitated a pose of a lengthy duration, and the film lost a good deal of its moisture; the nitrate of silver, thus becoming too much concentrated, dissolved a portion of the iodide, and diminished the sensitiveness of the film. By his new method of operating the nitrate of silver is concentrated to the proper degree only on evaporation. Thanks to this change, the exposure in the camera with a red glass has been reduced from thirty to six minutes in the sun, and under some circumstances an image may be produced in less than five minutes, and this, too, with lenses of by no means a rapid nature.

The heliochromic prints, or positives, are composed of images produced from the three clichés, under red, green, and violet screens; the impressions being taken upon coloured bichromated gelatine, and superposed by mounting. In printing, M. Ducos makes use of three pigmented papers, the first coloured with carmine, the second with a mixture of cadmium yellow and Indian yellow (chrome yellow being equally suitable), and the third paper with Prussian blue containing a slight addition of carmine.

After sensitizing, drying, and exposing to light, the pigmented paper is moistened and placed upon a glass plate, and developed by means of hot water. The monochromes thus obtained on glass plates are covered with a film of gelatine, and transferred to one and the same sheet of paper in the manner following. A gelatine bath is prepared by dissolving seven or eight grammes of gelatine in a litre of water. In this bath, which is too dilute to form a jelly when cold, the yellow monochrome is first of all immersed for some instants, and then a sheet of gelatinized paper is taken and plunged into the same bath, the gelatine side undermost. When the paper has been sufficiently saturated—that is to say, after a minute or two—the

monochrome image is withdrawn from the bath, together with the paper, and the two superposed and drained without employing a squeegee or other instrument. The adherence of the two surfaces soon becomes perfect, and any creases that may exist disappear of themselves afterwards.

When this desiccation is complete, the plate, covered with the yellow monochrome and gelatine paper, is again immersed in the bath; it remains for an hour, or longer even, according to the thickness of the paper; after this period the monochrome is withdrawn together with the plate, and they are separated in the same way as a carbon print.

To superpose this yellow monochrome upon the blue one, the latter is plunged into the same gelatine bath for about an hour and a quarter. The yellow monochrome, after being detached from the glass, is immersed again; the two monochromes are then withdrawn from the liquid one upon the other in the manner previously described. So that the outlines may coincide exactly, the blue is slipped over the yellow, while the print is examined as a transparency. To follow the operation in this way is very easy, because the thickness of the glass is interposed between the eye and the double image. The two monochromes are then allowed to dry spontaneously.

The third and last monochrome image is applied in the same way, the two monochromes already upon paper being cemented to the monochrome still upon glass. When completed, the heliographic image is placed in cold water to separate the glass plate; the print is then dried, after being stretched upon a frame, and is then trimmed and mounted upon cardboard.

To facilitate the separation of the monochromes from the glass, M. Ducois du Haaron recommends the introduction into the colourless gelatine of a very minute quantity of bichromate, about half per cent. compared to the gelatine dissolved, and further advises the exposure to full daylight of the films cemented together.

This imperceptible quantity of bichromate suffices to modify the nature of the gelatine pellicle, so as to give it an adhesive property, without which the clear portions of the image (by reason of their thinness) are prone to hold to the glass. Before immersing the monochromes in the gelatine bath, they should be first bathed in cold water, which removes from them the light brown tint which the light has imparted to the film.

It is easily understood that the polychromic image being constituted by three images superposed, each of them ought to be much less intense than a single print would be. The monochrome must, therefore, be weak in the half tones, and a concentrated bichromate bath, together with a short exposure to light and thorough washing in warm water, will give such a result.

Instead of pigmented tissue, use may be made of plates properly prepared with pigment, only in this case the printing must take place through the glass. The prints thus obtained do not lack delicacy if care be taken to use sunlight, and to place the printing frames at the bottom of a tube the interior of which is painted black, to prevent the action of lateral rays.

M. Ducois du Haaron, who is just now in Paris, and giving directions for the manufacture of apparatus and accessories which he has till now been in need of in the provincial town where he resides, has shown us several specimens of his process, which he proposes to present to the French Photographie Society at their first meeting. Among them is a reproduction from a portrait painted in the last century, and a landscape from nature, which are very remarkable. Although the prints are made up of thin monochromes only, all the colours composing them are very distinct, and the results are really most striking. At the same time, we ought to say that the specimens are of very small dimensions—about quarter-plate—and, so far as the printing is concerned, leave something to be

desired. It is on these points more especially that progress is desirable.

Chance has recently put into my hands a document which is of importance in reference to the history of photography. It is a note preserved by the officer of the fire brigade who directed the operations on the occasion of the fire at the Paris Diorama in 1838. It is well known that Daguerre was a distinguished artist, and painter of the Diorama. To show his peculiar genius, he constructed upon the Boulevard St. Martin, on the same spot where to-day may be seen the Prince Eugene Barracks, a vast building, next door to which he took up his abode. When the fire took place, it was generally believed that his laboratory was destroyed at the same time as his paintings, and that the discovery which was about to make him famous, and of which rumours had already got abroad, would be entirely lost, together with his apparatus, specimens, and manuscripts. The document to which we have referred gives some interesting details on the subject. The officer commanding the fire brigade stationed in the Boulevard St. Martin, having been informed that a fire had broken out at the Diorama, hastened at once to the scene, together with the detachment under his command. As soon as he arrived on the spot, Daguerre ran to him and besought him to let the Diorama burn, and to use all his efforts to prevent the flames from spreading to the fifth floor of the house adjoining.

It was an old house of sorry appearance, of which a great many existed at that time in the neighbourhood of the Faubourg du Temple, and the flames were already reaching the first floor. All the inhabitants had already left, and the place was quite deserted and abandoned, and nobody seemed to think it worthy of attention. But the agitation of Daguerre, and the vehemence with which he insisted upon his request, left no doubt of the gravity of the matter, especially as he was too much interested in the affair to give false information. The officer therefore carried out his desires, and, without abandoning the principal seat of the fire, directed the jets from two pumps to be played upon the house in question, and the effect of these were such as to preserve the building, so that after a little while the officer and two of his men were enabled to penetrate upstairs to the fifth floor. The stairs were so narrow and steep, and the air so stifling, that it was impossible for Daguerre to follow them, and, arrived at the top, they broke open with a blow from their hatchets the door which had been pointed out to them. This miserable little chamber was Daguerre's atelier. They found the optical instruments, drawings, manuscripts, &c., as also the apparatus, intact. All the objects were rapidly placed in boxes with care, and when Daguerre found his way upstairs shortly afterwards, and penetrated to his laboratory, his joy in finding the precious fruits of his long researches unconsumed and uninjured knew no bounds.

It was in this way that the publication of the discovery was rendered possible the following year by Francois Arago, and that the public was placed in possession of an invention which had such important results.

ERNEST LACAN.

#### A RAPID DRY-PLATE PROCESS.

BY PROFESSOR H. J. NEWTON.\*

At a previous meeting I alluded to the fact that a collodion containing a chloride was better adapted for making dry plates than ordinary bromo-iodized collodion, especially if alkaline development was to be used. In continuing my experiments in that direction I found that plates prepared with a collodion containing a chloride were peculiar, inasmuch that a plain pyrogallic acid solution would develop a picture with about the same exposure as that of a wet plate. The image was always very thin and delicate, but full of detail, and readily responded to the action of

\* Read before the Photographic Section of the American Institute.

acid pyro and silver, so that no great difficulty was experienced in obtaining negatives of sufficient density. I found, however, that a slight trace of alkali, with a trace also of bromide of potassium, facilitated the development. It brought up a much stronger negative at first, and much less labour was required to obtain the proper density.

I had at the same time compounded a new preservative, the result of experiments carried on at the same time, and which has much to do with the extreme sensitiveness of the plates. I therefore propose to give in detail the whole process, with the formula for the collodion which I have found to be the best.

First the collodion formula. I use

Alcohol and ether in equal parts.

Bromide of cadmium ... ..	1½	grs to the oz.
Chloride of calcium ... ..	1	„ „
Iodide of cadmium ... ..	4½	„ „

Dissolve the salts in the alcohol in the order given; when dissolved, add the cotton. A short-fibre cotton should be procured if possible. Five grains to the ounce will ordinarily be found to answer. If the cotton is perfectly free from acid, collodion so prepared will keep for a year or two without any change for the worse. Before using, it should be rendered an orange colour with a scale of iodine. I have made beautiful negatives with it when only a few hours old.

I would state here that I have compounded a collodion for out-door wet plates with the same salts in different proportions, using half a grain of the bromide, the same quantity of chloride, and five and a-half grains of iodine, which I designate my No. 2. The mixing of the No. 1 and No. 2 in equal quantities forms what I call my No. 3. In my experiments with some forty differently salted collodions, I do not hesitate to say that these are decidedly the most sensitive. I am sustained in my conclusions by some of our most experienced photographers, both in and out-door workers. The No. 2 is, however, preferred for out-door work to No. 1 or No. 3, unless the picture to be taken is mostly in shadow, when No. 1 or No. 3 would be more suitable.

In making dry plates, a bath should be used which gives good brilliant negatives when wet. The plates should remain in the bath about five minutes; when taken out they should be plunged into an upright bath of distilled water. If they are laid into a horizontal dish, the iodide of silver formed by the small portion of negative bath adhering to the surface of the plate, coming in contact with the water, will precipitate into the surface of the collodion film, and result in producing innumerable pin-holes when the plate is developed. There cannot be too much stress laid upon the importance of using *pure water* for the first washings. This has been reiterated by every successful dry plate worker who has written on the subject, and yet I frequently find photographers expressing disgust at the result of their efforts with dry plates, when failure has been due entirely to a disregard of this important injunction. When reliable distilled water cannot be procured, water obtained by melting ice will answer. Besides the upright bath, I use two horizontal dishes of distilled water. By so doing I keep four plates in the work, and finish one every five minutes, or the time it takes a plate in the negative bath, thereby losing no time. A plate is taken from the negative bath and placed in the upright water bath, another plate flowed with collodion, and placed in the negative bath. The plate in the upright water bath is then removed to one of the horizontal dishes. This is continued until both horizontal dishes contain plates, when there will be four plates in the work. I then take the first plate from the last horizontal dish and give it a slight washing under the tap, and then place it in a dish containing a four-grain solution of chloride of ammonium, where it remains until I remove a plate from the negative bath and coat another. The plate is then taken

from the salt solution, washed under the tap, and placed in a dish containing the preservative, where it is allowed to remain one or two minutes—the time is not material—it is then taken out, and the back wiped with a sponge and set up to dry.

I have found that the drying is much facilitated by wiping the back. I have observed that the collodion side of a negative never dries while the back is wet. This fact would be used to great advantage by those requiring long exposures with wet plates. By placing a wet piece of blotting-paper over the back of the sensitized plate the drying of the collodion film could be prevented for a long time. It is important that the drying of the plates should not be retarded, and the sooner the drying is effected under ordinary circumstances the better. The solution of chloride of ammonium can be used several times.

My preservative solution is made as follows:—

Water ... ..	10	ounces
Tannin ... ..	50	grains
Laudanum ... ..	1	drachm

The addition of laudanum to the tannin solution produces a precipitate of the gum in the tannin. I thought, at first, it was the opium contained in the laudanum; I found it, however, wholly insoluble in alcohol. I therefore concluded it came from the tannin solution. This precipitation should be filtered out, and then fifty grains of pulverized gum-arabic added. If the gum is added before the laudanum there will be no precipitate formed, and the resulting compound will not answer the same purpose.

After the solution has been again filtered it is ready for use. I have made good negatives with plates prepared by the foregoing process in five to ten seconds' exposure, which was quite as quick as a wet plate negative could be made under the same conditions.

To develop, I use two wide-mouth vials, holding about two ounces each. Into one I put one drop of a solution of aqua ammonia, half water, and one drop of a ten-grain solution of bromide of potassium; into the other about three-fourths of an ounce of a three-grain solution of pyrogallic acid. I first wash the plate thoroughly, and flow over it the plain pyro solution several times, and then pour it into the bottle containing the ammonia and bromide of potassium, and then flow again over the plate. The image comes up instantly, full of detail, if the exposure has been rightly timed. When this development has proceeded far enough, it is washed off, and the plate flowed with a weak solution of citric or acetic acid to neutralize the ammonia. The image can then be brought to the proper strength, either by the ordinary acid pyro solution, or with pyrogallic acid and tannin. I use the latter, as it is the most convenient. It keeps for a long time, and is the most energetic. I mix it, six grains each, to the ounce of pyro and tannin; usually using half that strength. It is, however, very convenient to have it the full strength, as it is a powerful developer and gives fine negatives with these plates without the alkali, giving about twice the exposure. I fix the negatives in a strong hypo solution, made a little acid with acetic acid. The addition of a small quantity of gold and silver to the hypo will prevent the reduction of the negative in fixing.

There has been some objection to gum-arabic in the preservative, on account of a tendency which the negatives have to blister when being developed where it is used. I have experienced, however, no trouble of this kind, which may be due to the exceeding small quantity of alkali employed. If, however, any should object to using the gum, they will find an excellent substitute in sugar of milk ten grains and grape-sugar five grains to the ounce of preservative. I always use albumen (sixteen ounces of water to the albumen from one egg) for a substratum for my plates, and have experienced no trouble from blisters with either the gum or sugar of milk.

## Correspondence.

## IMPROVING NEGATIVES.

DEAR SIR,—As there is so much done at the present time in negative retouching, perhaps you would like to try the following plan, which, if you approve, may be recommended to your numerous readers:—

Take a good B or BB pencil, and with a sharp penknife scrape off some of the lead free from grit, and by means of a small stump (say No. 1 or 2, which may be had of any dealer in artist's materials), apply a little of it to any part of the negative which requires intensifying, and gently rub it on. If the negative is an old one, and the varnish quite hard and dry, breathe on it before applying the lead. Faulty places in backgrounds may be much improved, and it is especially useful in giving delicacy to the face when the negative is not sufficiently dense.

It is possible others have already tried this method, but I am not aware of it.—I am, dear sir, yours truly,  
*Nulsea, nr. Bristol, 7th October.* JOHN D. WAYMOUTH.

## IMAGE BEFORE DEVELOPING.

SIR,—In reading last week's News I find an account of an undeveloped dry plate showing a visible image by reflected light, and being described as an unusual case I am led to trouble you with my experience in that line.

In the early part of August last, knowing I was going to the seaside for a week or two, I thought of taking the camera with me, and having last year got into trouble with the wet process (or, rather, with the materials), I thought of trying the dry this time, and did so with no better success.

On August 11th I prepared about a dozen each of quarter and half plates by a process described by Mr. Davies in the PHOTOGRAPHIC NEWS of June 12th, 1874, page 285. I carried out all the instructions to the best of my ability, the only uncertain thing being that I used Allsopp's bitter ale (strong sweet ale is described in the formula). After the plates had been prepared a few days, I tried one or two behind a negative in a printing frame without any kind of backing, and was quite surprised, on removing the plate after sixteen seconds' exposure, to find an impression quite distinct by reflected light. I then tried to develop it more than it was, but could make no job of it, the plate getting fogged all over after a minute or two.

I have exposed the plates several times since with the same results—in fact, this morning I cut a plate in three pieces, and exposed two of them each about two minutes, and they showed the visible image just the same as the others; but I cannot make a job of the developing. I have about two or three plates left, and shall save them till a future time.—Yours obediently,  
B. D.

*London, October 13th.*

[The presence of a visible image on dry plates coated with an organic preservative is by no means uncommon: it has, indeed, occasionally been seen with a wet plate. As a rule, it indicates over-exposure. In our correspondent's case of contact printing we think it indicates over-exposure, and the fogging on development is, doubtless, from the same cause.—Ed.]

## THE CRAWSHAY AWARDS.

DEAR SIR,—Is there not some error in the award of the Crawshay prize for enlargements?

In the published circular containing the final announcement of the conditions to be observed by intending competitors, it is expressly stated that "slight touching or spotting, such as is now customary to apply to negatives or prints that are not professedly retouched, is allowed, but worked-up prints will be disqualified. This having been so clearly and distinctly insisted upon, it is a matter of the greatest surprise to many photographers, as well as myself,

to find the prize awarded for professedly worked-up enlargements, such enlargements being advertised as exhibited in illustration of a patented method of finishing or working up ordinary photographs; the enlarged photographs themselves not being the work of the exhibitor, who only claims the method of finishing. I have no word to say in dispraise of Mr. Ferranti's process for finishing photographs, my only object being to call attention to the fact that the judges have entirely ignored the terms laid down by Mr. Crawshay, and accepted as binding by the competitors.

Under these circumstances I enter my protest against the award to Mr. Ferranti, the pictures shown by him being clearly disqualified, according to the plainly expressed terms of the invitation to competitors.—I am, dear sir, yours truly,  
*Hackney, October 14.* B. J. EDWARDS.

[Mr. Edwards is curiously in error. He mixes up, in an unjustifiable manner, an advertisement by Mr. Ferranti, in relation to a mode of finishing photographs, with Mr. Ferranti's pictures sent in to compete for the prize for enlargements. He then proceeds to affirm that the enlargements in question were not Mr. Ferranti's own work. This may be so, or not; but the judges have no more evidence of the matter than they have that the pictures sent in by any competitor were or were not his own work. Finally, he quotes as Mr. Crawshay's conditions certain conditions which Mr. Crawshay did not make. The passage quoted is from the advertisement of last year, referring to last year's pictures, and, by some inadvertence, copied in a circular sent out by the Photographic Society a few days before the exhibition. Not one of Mr. Crawshay's announcements in relation to the present competition (of which several have appeared during the year) make any statement as to retouched prints being disqualified.—Ed.]

## TECHNICAL EXHIBITION MEETING OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

DEAR SIR,—Will you kindly again permit me to announce that the Technical Exhibition Meeting of the South London Photographic Society will take place at the Cambridge Hall, Newman Street, Oxford Street, on Thursday evening, October 29th, at seven o'clock. This meeting is intended for the exhibition of apparatus and appliances, the reading of short papers, illustrated with specimens, and demonstration of experiments and processes, together with the exhibition of results of secret and patented processes. The following rules have been drawn up by the committee for the regulation of the business:—

All papers to be read must be received by the secretary at his residence on or before the morning of the 28th.

Exhibitors wishing to work processes or experiments must acquaint the secretary with the probable length of time required.

Questions may be asked, and information given, in relation to the matter before the meeting, but no discussion will be permitted.

Every article must have attached to it an explanatory label, or short description of its use.

All articles must be sent carriage paid (with instructions for return) to the place of meeting, not later than three o'clock on the 28th.

Any further explanation may be had by applying to the secretary.—Yours faithfully, EDWIN COCKING, Hon. Sec.

*57, Queen's Road, Peckham, S.E.*

## Proceedings of Societies.

## EDINBURGH PHOTOGRAPHIC SOCIETY.

The twelfth ordinary meeting of this society was held at 5, St. Andrew Square, on the evening of Wednesday, the 7th inst., Mr. R. G. MUN, president, in the chair.

The minutes of the previous and out-door meetings were read and approved, and Messrs. Alexander Asher, John Thompson, and

Alexander Henderson (of Montreal) were admitted ordinary members.

Mr. TURNBULL read a paper, entitled "A Few Words on the Beer and Albumen Process" (see page 495.)

Mr. MATHESON had wrought the process almost exclusively, and succeeded better with it than with any other. He had tried the addition of silver, as now recommended by Mr. Davies, but he really could not find any difference between plates prepared with it, and those prepared in the older way. He called the attention of the meeting to what he considered a curious fact—*i.e.*, that at the time the process was introduced by Mr. Davies, he got pictures with exposures of two and three minutes; but that gradually the necessary exposure had been increased, until at the present time at least three times as long was required. He wondered whether the beer made now differed from that of six or eight years ago.

Mr. YERBURY had not much experience in dry plate work, but what he had done was with Davies' process. He had tried both with and without the addition of silver, and was quite certain that the former was the best. The plates were not only more rapid, but the resulting negatives were of better quality.

Dr. THOMPSON had not done much in dry plates this season, but what he had, had been by Davies' method, and he had found it in every way satisfactory. He had worked exactly according to the directions given by Mr. Davies, except that he had somewhat raised the temperature of the plate during development. His plan was to dip the plate in a tray of equal parts of alcohol and water, and, after washing, to place it in a dish of water, heated to about 45° C. It was then transferred to a solution of plain pyrogallic acid, and the development proceeded as rapidly as in ordinary iron development.

Dr. NICOL thought Mr. Turnbull was mistaken in supposing that the addition of ammonia to albumen resulted in a mere mechanical mixture. There was in reality a very complicated reaction, which, amongst other results, gave a limpidity to the albumen, by the partial breaking up of the cellulose of which it was partly composed. He had experimented more or less with nearly every dry process that had been introduced, and had produced fairly good negatives with them all; but when he wanted pictures, rather than experiments, he had for years trusted to Davies' in preference to all others. He could easily understand how Mr. Turnbull might make a series of comparative experiments, and come to the conclusion that the addition of silver gave no additional sensitiveness. It should, however, be remembered that very much, in all processes, lay in the development, and that it was not at all unlikely that two modifications, developed in the same way, would give only similar results, while, by some alteration in the method of bringing out the image, one might be found very much more rapid than the other. In the case in point, he knew that the plates prepared with silver in the beer could, by very slight modification in the method of developing, bear a reduction of nearly a half in the time of exposure. He quite agreed with Mr. Matheson in thinking that the plates required a much longer exposure now than they did ten years ago, but he did not think it was caused by any alteration in the quality of the material used. He was rather inclined to attribute it to a generally higher cultivation of the knowledge of what really constituted a good negative, as he believed that many of the hard, patched negatives—the result of the short exposures of that period—would not now be thought worth varnishing.

Mr. DAVIES said that he had never said that the beer and albumen was a rapid process, and if it had been, he would have had nothing to do with it. He did not like rapid dry processes, as whenever we have great sensitiveness, we have, as a natural result, great uncertainty. He had no doubt that Mr. Turnbull's experiments were quite correct so far as he had gone, but he believed that nearly everything in connection with rapidity depended on the development, or on the addition to the film of something by which it would be promoted; and he thought that the silver which he added to the beer acted in that way. He had brought one or two negatives, however, to show what could be done in the direction of rapidity with beer and albumen, if rapidity was really wanted. He then handed round three pairs of negatives, one of each being by beer and albumen, and one by wet collodion. Each pair had been exposed simultaneously, the preservative of the first and second being made decidedly alkaline, and the third, after preparation, thoroughly fumed with ammonia. The first two had been exposed ten seconds, and were both under-exposed, but the dry plate contained considerably more detail than the wet. The second pair had received an exposure of eighteen seconds; both were fully out, but the dry plate was decidedly the better of

the two. The third pair, the dry one of which had been fumed, were exposed for only one and a-half seconds; the wet plate was considerably under-exposed, but the dry one showed full detail and quite sufficient printing density, the clouds especially being very fine. In reply to several questions, Mr. Davies said that he had not been able to make many experiments as yet with the fumed plates. He found, however, that after fuming, the plates required to stand for at least four hours before exposure. He promised to continue his experiments, and report the results at a future meeting.

Mr. DAVIES then read a paper, "The Spirit of the Journals" (see page 496), which created some amusement, and for which he received a vote of thanks. A donation of a number of very fine prints from Mr. Henderson, of Montreal, was presented to the album of the society; and Mr. Yerbury also contributed some fine specimens of his work at one of the outdoor meetings, one of them including a capital group of the members present.

On the motion of Mr. W. Neilson, votes of thanks were awarded to Mr. Turnbull for his paper, and to Messrs. Henderson and Yerbury for their donations, and the meeting shortly afterwards adjourned till the first Wednesday in November, when the annual general meeting will take place.

#### THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The monthly meeting of the board of management was held at the offices, 174, Fleet Street, on Wednesday evening, October 7th, Mr. W. S. Bird in the chair. After the routine business had been disposed of, Mr. Pritchard, the treasurer, announced the receipt of five guineas from Mr. Bedford, who has signified his intention of becoming an annual subscriber of one guinea.

The SECRETARY announced the receipt of twelve 12 by 10 photographs from Mr. Warwick Brooks, of Manchester; twenty-five large and thirty-six cartes from Mr. Rejlander; and thirty-six assorted sizes from Mr. Stillman, as prizes in the Art Union Distribution, which a sub-committee were appointed to organise and carry out.

The secretary was, on the motion of Mr. Attwood, instructed to write to the council of the Photographic Society of Great Britain, to ask if they would grant one day during the forthcoming exhibition for the benefit of the funds of the association.

Mr. Bird having vacated the chair, he was elected chairman of the board of management, vice Mr. Croughton, who had resigned on account of leaving London for Lowestoft. Mr. Bird having resumed the chair, the secretary presented an application, duly signed by two members of the association, from a photographer for relief. The application stated that he had been in business for himself nine and a-half years, and was now in distress on account of an illness of eighteen months, the whole of which time he had been unable to do much work. He has a wife and eight children (the eldest thirteen) dependent upon him. All his apparatus had been pawned for food, and his landlord had distrained for rent. Although not a member of the association, the board were unanimously of opinion that it was a case worthy of consideration, and, after hearing further particulars from the two members who had signed the application, the sum of £5 was voted to him.

Fourteen new members were proposed for election, and on the secretary reporting that their references were satisfactory, they were duly admitted as members.

The secretary, who had been acting as treasurer pro tem., on handing over the banking accounts to Mr. Pritchard, the treasurer, submitted a balance sheet of affairs which showed that since the commencement of the movement the receipts had been £15 14s. 2d. The payments for advertising, stationery, rent, &c., £21 18s. 8d., leaving a balance in the London and County Bank of £22 19s. 6d., and in the hands of the secretary, 16s.

This concluded the business, and the board adjourned till the 4th of November.

W. T. WILKINSON, Secretary.  
14, South Street, Bromley, Kent.

#### Talk in the Studio.

PHOTOGRAPHIC REGISTRATION OF OCEAN TEMPERATURE.—Dr. Neumayer has presented to the Geographical Society of Berlin a photographic apparatus for determining the temperature of the currents at the greatest depths of the ocean. There are many ingenious peculiarities about the apparatus, but it is essentially a thermometer fixed in a copper bottle, with a piece of photographic paper on one side of it, and charcoal points as the terminal poles of an electrical apparatus. At any desired

depth the connection is made with the battery, and the electric light produced marks the height of the mercury in the thermometer on the photographic paper.

**THE WEATHER IN ENAMELLING PRINTS.**—Mr. I. B. Wobster says, in the *Philadelphia Photographer*:—"To insure success great care should be taken in every branch of the process. I find that several different methods for preparing the plate (glass) for enamelling are published, and presume that all are equally good in the hands of those who use them. What I particularly wish to call attention to is the fact of such a great difference in securing a complete divorcement in all cases; you may for ten days produce perfect surfaces in every instance, and all at once you lose everything in consequence of the print adhering to the glass. Now the query comes up, why the difference? Watch the barometer, and act according to its rising or falling propensities. To insure a perfect clearing from the plate, the photograph must be perfectly dry before the mount is applied to it, and then both must be thoroughly dried before an attempt is made to separate them. Artificial heat is not altogether reliable unless applied as a general heater—for instance, similar to the heat of an oven, and that, too, very gradual. A violent heat will spoil all. A 'hint to the wise being sufficient,' I forbear to enlarge."

**SUBSTITUTE FOR AN ARGENTOMETER.**—A correspondent of the *English Mechanic* says:—"Obtain an Allsopp's Minim Meter, which is a glass instrument, like a syringe, graduated up to 60 minims (480 of which equal one ounce of distilled water at 60° Fah.). Make a stock solution of chloride of sodium 34½ grains to 1 ounce of distilled water. Then take up, by means of the minim meter, 100 minims of the bath to be tested, and convey it to a test tube; rinse the minim meter with pure water, take up 60 minims of the solution of chloride of sodium, and then eject it carefully into the 100 minims of bath. As the drops of chloride of sodium solution pass into the nitrate of silver solution a white flocculent precipitate of chloride of silver will be formed. Hold the test tube by the top, and shake it briskly sideways; this causes the precipitate to settle rapidly. Be careful not to add too much chloride of sodium at first, as the chloride of silver is soluble in an excess. When the liquid above the precipitate in the tube appears of a bluish-white or milky tinge, it is very near saturation, and the test solution should be added drop by drop until no precipitate or cloudiness appears. The process is then complete, the number of minims of test solution expended representing the strength of the bath in grains per ounce—that is, supposing 20 minims of test solution are left unused, then 40 minims have been expended, and the bath is, therefore, 40 grains to the ounce. Of course, if the bath is more than 60 grains, the 60 minims of test will be used, and more will be required from the stock. The above process is perfectly reliable; the minim meter is useful for other purposes. The argentometer costs twice as much, and is not reliable—except with a newly made bath, when it is not required, as the strength is known. The value of the nitrate of silver used will probably never exceed one penny for each test, and the chloride of silver produced can be put with the other residues, to be reduced at home or sent to the refiners, as convenient."

## To Correspondents.

**MARSHAL HENRY.**—Artists' lay figures are of various kinds and of every size, from about a foot high to life-size. They are also of different degrees of complexity and value. The best are perfectly articulated like a human figure, and may be made to assume almost any position of limb, body, or head, so that when duly draped they could scarcely be distinguished from a human figure. There is no attempt made, as a rule, to give a face of any special character, and for expression you must depend entirely on the living model. Lay figures can be obtained from all dealers in artists' materials, and the prices will vary from a few shillings to a few pounds.

**H. M. M.**—The ordinary method of making chloride of gold by means of nitro-hydrochloric acid may be applied to alloyed samples as well as to pure gold. If the alloy be silver, it will be thrown down as insoluble chloride in the process; if it be copper, it will remain in solution, and will do no harm. We have often given instructions in the *NEWS* and in the *YEAR-BOOKS* for making chloride of gold. If you cannot find a reference, write again, and we will help you.

**W. A. B.**—If you had carefully read the articles in question, you would have seen that in the third or fourth of them we explained that *sai soda* is the American colloquialism for common carbonate of soda.

**ENAMEL.**—Unless you are familiar with the operations in collodion making, you can buy what you require better and cheaper. If you can buy good pyroxyline, which should be made at a low temperature, and so give a horny collodion, you may succeed. Take methylated ether and methylated spirit in equal proportions, and dissolve pyroxyline therein. It is difficult to state definite proportions, as this will be much governed by the quality of the pyroxyline. About four or five grains to each ounce of mixed solvents will answer with some samples, whilst with others nearly double the proportion may be required.

**J. L.**—We are not aware of any method whereby you can secure a certain title, like that you mention, for sole application to your studio.

**COLLODIO-BROMIDE.**—You had better follow the details given by Mr. Cooper in our *YEAR-BOOK*. For the emulsion you may use the formula you mention. The uranium salt is added when the emulsion is mixed.

**BENEFICIO.**—The *NEWS* will doubtless aid you best in securing the material you require; or the *YEAR-BOOK* will give you much of it in a condensed form. If you can obtain a copy of the *British Quarterly Review* for October, 1867, you will find almost everything in the form you require it. The article was printed in various articles of the *NEWS* in the volume for 1867.

**THE CRAWSHAY COMPETITION.**—The "Little Man in Green" sends us a long and interesting letter setting forth his grievances as a disappointed man, misled by the circular issued by the Photographic Society. Our correspondent states that he followed this circular accurately, and then found that his pictures were disqualified by their size. He says:—"I suppose I am not the only photographer who has been misled over the No. 3 prize in the Crawshay competition. I am quite aware that, seeing that the announcement in the circular of the 19th September was at variance with the advertisement in the *YEAR-BOOK*, I ought to have paused awhile. But I am one of those who do things impulsively, and as time was short there was no room or time to doubt but that the circular meant what it said. So I set to work and finished three 5½-inch heads, and was happy—supremely so; so happy, in fact, that I told my wife I should take my holiday at once, and run over to Paris and see how *nos intimes* were getting on. 'I have been and gone and done it,' as the boy said when he broke the lamp. I enjoyed myself awfully, did everything and everywhere, and was done by everybody everywhere. Still, if I had a sad moment, that very sadness was pleasant, for my thoughts would revert to my darling 5½-inch heads, and visions of Mr. Crawshay's cheque for £25 possibly lured me on into expenditure just a little over what my home ruler advised me to indulge in. I have returned, and only to find my prospects blasted, and my fondest and most cherished hopes crushed. Misfits by one inch and a-quarter. Thanks to whom? But no; though *Bonhastes Furioso* was a fool to me when the *NEWS* was brought me, I must try and get cool. It will be some time ere I am fit for civilized society, I feel sure—I am so very impulsive. I shall now return to my country home, as London has, for the moment, no charms for me; and I shall commit my pictures to the flames, and then, when this act of cremation has been accomplished, I shall return to town, and pull your house in Suffolk Street pell-mell about your ears in the interest of my 'brudder blacks' who may chance to be hung within those walls. Let the judges look to it. This year I meant exhibiting, as I see a chance of impartiality, which will be, in my estimation, a refreshing treat. Let Justice, for a change, be deaf instead of blind, and so not able to listen to the voice of the charmer, but to look at the general artistic effects, and the simplicity with which those effects are produced, and so encourage gentlemen in our profession to aim at something higher than the mere perfecting of the most mechanical branch of their studio work. I think the end should be held to justify the means, and then our exhibitions would contain gems indeed. Last year's exhibition of direct life-sized ghosts proved to me that if a man does not want to frighten his customers, he must not touch them; and experience teaches me that, though enlarging be done for the trade in ever so wholesale and complete a manner, only about once a year does a large head come to hand that will bear looking at ten feet off without working up. Now, Mr. Editor, I will conclude. I could say more, but shall wait till Suffolk Street opens, when, as an impartial observer, I may trouble you again." We sympathize much with the "little man," but he must admit that all Mr. Crawshay's announcements have been precise enough, and that it was, to say the least, unwise to leave until the end of September the production of specimens which must be delivered in the beginning of October. Some other competitors have complained of being misled in other points by the circular in question. It is to be regretted. The errors have arisen, we have reason to believe, by the conditions of a former year having been, by some inadvertence, copied in the circular in question; but no one can be justified in ignoring or disregarding all the previous announcements, which were authoritative, clear, and precise.

**A PRINT CUTTER.**—We have received by post a revolving knife for cutting prints, without any letter of advice from any one. Several Correspondents in our next.

## The Photographic News, October 23, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### A PRACTICAL PHOTOTYPE PROCESS—PHOTOGRAPHY IN THE NAVY—DIFFUSION OF ORDERS BY PHOTOGRAPHY—PAINTING ON GLASS BY MEANS OF ALBUMEN.

*A Practical Phototype Process.*—We hear that a French phototype process is to be employed in London shortly to aid in the printing of an illustrated journal that will appear about December next. So far as we have learnt, the process does no more than many others we have heard of, but we suppose that it is simpler and more certain in its results, for the vast number of specimens we have seen were certainly of a most satisfactory kind. Although we are not familiar with the precise details of the method, which seems to be kept somewhat of a secret, we may state that by its means the expensive process of engraving on wood or other material is altogether avoided. Most people know that the cutting of a wood block generally costs as much as the sketching by the artist, so that if the latter charges five or six pounds for his labour, the engraving will come to as much more. Now the phototype process in question does the engraver's work, for as soon as the artist has completed his sketch everything else is a mere matter of detail; and instead of five or six pounds being expended in the production of the block, fifteen or twenty shillings is the utmost it will cost. The sketch—which is, of course, a linear one—drawn by a very black pencil on white paper, is simply photographed, transferred to stone, and re-transferred afterwards to zinc, from which the impressions are taken. The prints are not, of course, so sharply defined as if they were impressions from a finely-cut wood block, but they are, nevertheless, very perfect, and they render possible what before was an impossibility: in other words, a publisher of a newspaper can afford to give six or seven guineas for a block, while ten or twelve would be quite beyond his means, for in the latter case he could never hope for a profitable return. But photography, in taking the place of the wood engraver, does more than this: it removes the great grievance under which most artists suffer. They are always at the mercy of the graver, for let their outlines be ever so delicate, and their lines and shading of the most perfect kind, a clumsy or ill-educated engraver may ruin the whole work. The engraver is generally somewhat of an artist, too, but if his ideas do not coincide with those of the sketcher the efforts of the latter are more or less in vain. Although, therefore, the results may be somewhat inferior to woodcuts, this new process will find great favour among artists in black and white, who may be certain that their pictures will, when finished, never be manipulated by any other hands than their own. Should we become more familiar with the details of the process, we shall not fail to communicate them to our readers.

*Photography in the Navy.*—It seems that our sailors are to be taught photography in future, and arrangements have been made at the Royal Naval College at Greenwich for instruction to be given in the art. This is exceedingly gratifying intelligence, for the college has but recently started into existence, and the curriculum of studies to be pursued by the lieutenants and sub-lieutenants has not yet been completely fixed. There cannot be a doubt of the importance of our vessels, and especially those stationed abroad, having an officer on board acquainted with photography, and furnished with all the instruments and requisites for the purpose; and as to fitting up a dark room in the hold, there would be but little difficulty in the matter, for obscurity is plentiful everywhere at and below the water-line. It would be no easy task, probably, to secure pictures of coast scenery, but such pictures of prominences, rocks, beacons, &c., would be invaluable additions to a chart for purposes of verification. Our corps of Royal Engineers have a certain percentage of photographers among them, and it is certainly well that our

Navy, also, should know something of so useful an art. Our sailor prince, the Duke of Edinburgh, is well known to be an accomplished photographer.

*Diffusion of Orders by Photography.*—At the head of every regiment, marching in front of the band, may be seen a little body of stalwart men, with long beards, carrying axes, spades, saws, and other useful implements. These, as our readers know, are called pioneers, and it has recently been decided by the Horse Guards to modify the equipment of these men. Unfortunately, however, there are scarcely two of them dressed alike, and the complicated instructions that would have to be issued, therefore, as to how this one is to carry his axe, another his saw, and how the tools are to be adjusted in reference to the new valise equipment that our soldiers wear in place of the old knapsack, would be very lengthy, and possibly somewhat unintelligible. A series of ten photographs, cabinet size, one of each man, has, however, been executed, the models being pioneers carefully dressed in their new appointments arranged as if on parade. Most of us are aware of the scrupulous attention paid to the dress of a soldier, and have seen, when a guard turns out, the serjeant move slowly up and down the ranks to inspect them, arranging a buckle here and a strap there, ready for the arrival of the officer. Such a photograph of a pioneer dressed accurately for parade, with each tag and buckle in its place, and faultlessly accounted in every particular, is all that commanding officers of regiments at foreign stations require to ensure the new appointments forwarded to them being worn in the fashion approved of at the Horse Guards, and any further instructions in the matter are quite unnecessary. This is a useful application of our art, well worthy noting.

*Painting on Glass by Means of Albumen.*—To enable you to paint upon glass there are few things so serviceable as albumen, or a solution thereof. By coating the reverse of a negative in this way, you at once permit of any pigment or other material being readily applied with a brush, supposing you wish to stop out or protect certain parts in printing. For colouring photographic transparencies for employment in the magic lantern, the use of albumen will be found very handy; and if the pigments are inclined to flow, as is the case with some of them, the admixture of a little gum suffices to prevent any such inconvenience. To protect a negative in printing, when it is not desirable to tamper with the original cliché, a piece of plain glass may be albumenized, and having been placed properly in juxtaposition with the negative, it is painted in any way that may suit the purpose. Albumen, being quite transparent, is preferable to any of the retouching varnishes, which usually contain a yellow lac in solution.

### THE PRACTICAL PRINTER IN AMERICA XII.

#### MODIFYING AND RETOUCHING NEGATIVES—(continued).

*Intensity.*—In glancing through a negative the intensity of it is also to be thought of, because it is necessary to adopt a certain mode of treatment for such a negative, whether it is intense, weak, or medium.

"An intense negative, as shown under the head of Printing Intense Negatives, is so called on account of the whites of the negatives, such as the face, hands, arms, &c. (when viewed by transmitted light) being quite dense; more or less so, according to the degree of intensity. Such a negative will yield prints that will be correspondingly light. When the negative is too intense, the whites of the prints will be what is termed 'chalky,' and if the exposure of the print is so far continued as to print in detail on those whites, then the shadows will print too black, thus making a decided black and white print. This is, however, treated under the head of Printing Intense Negatives. My object at present is to state the treatment of intense negatives before printing. As such negatives should be printed quickly, they should not have any colour on the

back of them, to take out shadows, &c., as described above, because it will then be necessary to delay the time of printing them a little, to prevent this colour from printing a harsh edge on the prints, as it will certainly do if the negatives are placed in the direct rays of the sunlight. Fill up these places, if necessary, with lead from the pencil on the varnished side of the negatives. If one coat of varnish will not take enough lead, then varnish again with a thin varnish, and then this new surface will probably take all the lead that is necessary. If, however, this will not answer, then blue-paint the negative, and print in strong sunlight, after having covered the printing-frame with one or more ground glasses, and even with a tissue paper, if it is found necessary. In printing intense negatives, print more for the shadows than for the lights.

"*Weakness.*—Weakness in negatives is the contrary to that which is described above, in relation to intensity. Weak negatives are very thin, *i.e.*, they are semi-opaque, or have more transparent lights than an intense negative, and when held to the light, objects beyond can be distinctly seen through the densest parts. Of course the rays of the sun would pass through such a negative more quickly than it would an intense one. The beginner must remember that the quicker the light passes through the negative the less bold will the result be.

"The methods of treatment for such negatives are very numerous. I have frequently blue-painted the whole of a face and hands of such negatives (with the exception, of course, of the eyes and shadows in the former) so as to permit deeper printing of the hair, dress, &c., while the face and hands are printing, thus making the prints bolder than they would be if it were not done. This in a great degree prevents flatness, as the resemblance between the light, shades, background, hair, dress, &c., is not so noticeable. If the background prints about like the figure, the prints can be greatly improved by printing vignettes from the negatives.

"Flowing these negatives on the back with yellow shellac varnish, and then scraping away those parts of the varnish which cover the hair, eyes, and the shadows under the chin, &c., is said to be very effective, as it permits the shadows and those parts of the negative which should print dark to print a shade darker than they would have printed before this treatment.

"Printing under yellow and blue tissue-paper is sometimes very good, but the prints do not work so well in the further operations as they would if they were printed under white, and not coloured paper.

"Printing under a ground glass laid flat on the back of the negative, ground side down, or a piece of porcelain glass, or printing in deep shade, are all very good for weak negatives.

"The advantages and disadvantages of what has been said about weak negatives and their treatment will be described more at length under the head of Printing Weak Negatives.

"*Draperies.*—One of the most important parts of a negative—to the ladies, at least—is the dress, &c., and upon this often depends solely their liking or disliking the photographs. Wrinkles in dresses, especially about the upper part of the body, are to be carefully prevented from printing if the wrinkles spoil the beauty of their otherwise fine form. Never, however, touch them if they do not spoil the figure. If the figure is a standing one, and there are many wrinkles about the waist of a dress, caused by an ill-fit on the part of the dressmaker, they should be taken out. This can be done with the lead-pencil. Does the lace-collar show well? If not, touch up the lacework, or, better still, send the negative again to the retoucher and get him to do it. All of these little things should be looked at by the printer before he prints from his negatives, and if there should be anything that you notice, and which escaped the notice of the retoucher, then you should never fail to get the retoucher to improve them, by a little more work, before you print a single proof from the negative.

Are the dresses in the negatives white? If they are, do you think that they will print well? Draw your pencil along the tops of the folds, so as to make the dress print bold, by having some contrast between the lights and slight shades. The above answers for a dress that has been about rightly exposed; but for an overtimed one, after the face, hands, &c., of the lady are printed enough, take a cloth, and, placing the negative-frame out in the sunlight, keep moving it over those parts of the negative and let the dress print still more. This is sometimes a tedious operation, but a very good one.

"The negative, if you choose, can be printed by placing first one thickness of tissue paper over the whole negative, but on to the outside of the printing-board and over the head, hands, &c., of the negatives paste (if possible also on the board, but over the other tissues at any rate) several other tissues cut to the size of the places that you wish to prevent from overprinting, *viz.*, the face, hands, &c. These pieces of tissue paper should be pasted on the other whole pieces of tissue and directly over the places to be shaded. Do not place paste over all parts of the small pieces of tissue that are to be placed on the boards, but just touch the pieces sufficiently to make them stick to the rest of the paper. It is not necessary to have these pieces lay so very smoothly, and it will not matter much if the edges should happen to curl up slightly. Print face to the sunlight.

"This treatment will permit the dress to print darker without the tedious operation of shading by hand the face of the negative to prevent it from overprinting. This is particularly advantageous when a dozen or two prints are to be printed from this negative, and all the time and trouble that is required is only while printing the first print, as the rest of the order can be printed like a plain print. After the order is printed, the tissue paper can easily be packed away in an envelope on the glass side of the negative, and thus saved for future use. Dark dresses should sometimes be permitted to print after the face and other parts of the whites—such as the face, hands, &c.—are done, so as to obtain fine, rich draperies.

"Are there any tufts of hair projecting out beyond the head, and which you think do not look well? If there are, touch them out with the lead-pencil. Are the frizzles on the lady's forehead regular, and do they look pretty? Can the hair be improved in any other way than what has been mentioned? Are the frowns removed as much as they should be, taking into consideration the age of the subject? How are the deep, heavy lines in the face; are they all right? The hollow cheeks, cheekbones, and the ears; how are they? Do the veins on the hands and the cords in the neck need 'doctoring'?

"Since we have examined about all parts of the negatives before placing them out to print, we will watch and notice to see if the places doctored are properly done; that the prints are as bold and brilliant, yet as soft, as they should be; and if there is as much detail in the prints as we wish."

#### THE PRESS AND THE EXHIBITION.

THE comments of the press upon the Exhibition have not, up to the present time, been so numerous as on former occasions, but have for the most part been highly complimentary. According to our custom, we place on record such notices as come under our attention.

(From THE MORNING ADVERTISER.)

Right were those, indeed, who used to predict, in the early days of Talbotype work, when the tentative steps of the artistic explorers over ground where they were met at every turn by the difficulties of chemistry, a science very little known to them, that the art was in its infancy. The pallid, washed-out specimens of what we may fancifully call prehistoric photography—lent the council for this occasion by the president, Mr. Spiller, F.C.S., and numbered 408, 412, 415, 416, reminding us very comically of our early studies—give rise to a reverent thought of Fox Talbot, and a feeling of gratitude that it has been permitted to

us to witness the splendid development around. The council, no doubt, found a somewhat heavy task before them if they took possession of this ample suite of rooms with any idea of covering the walls; but it must be admitted that they have gone far towards that end. They have covered, in fact, all the space available in the principal gallery and three smaller ones, and no justice could have been done to another row above the line had they attempted the experiment. Now let us take notice, in the first place, of the "Crawshay competition" works, in portrait and landscape—this being the principal feature of the exhibition—although we shall have to deviate from the numerical order of the catalogue—in fact, to begin in the middle. Most agreeably for the society of which he is a member, Mr. Robert H. Crawshay, a master of high-class photography, has been so dealt with by circumstances as to be in a position not merely to indulge his taste for the pursuit to the utmost, but also generously to stimulate the ardour of his fellow-workmen in the craft. He has this year given for competition (and not for the first time) certain Crawshay prizes as follows:—The first is £50 for the best collection of three photographs of heads taken direct from life, not less in size than 20 inches by 16, and the heads not more than 8, or less than 7, inches in height. The second is £25 for the second best collection of three heads. The third is £25 for the best collection of three heads 15 inches by 12 over all, and the heads not less than 4½ inches long. Prize the fourth is £12 for the second best similar collection. The fifth is £25 for the best enlargement, not less in size than 20 inches by 16, by any method. The sixth is £25 for the best collection of three landscapes not less than 10 by 8 inches; and the seventh £12 for the second best ditto. The eighth is for the best landscape of any size from nature. This is a very open race, with many fit starters in the profession, to the second of whom Mr. Crawshay has allotted a consolatory £5 prize. For the portrait prizes there were twelve or thirteen competitors, sending fifty works, most of them elaborate, many of them beautiful, some even too conspicuously so—but this is quite a matter of taste. One might as well desire a lovely woman to be plain as ask her to disguise her charms in shadow and rags with any good grace; therefore, of course, the majority of sun-portraits continue to reflect, immortalise, and enhance the charms of the toilettes as well as of the sitters, although such highly decorated objects do not find equal favour with the judges. The first prize has fallen to Messrs. Chaffin and Son, of Yeovil, who exhibit six portraits, three in the two first classes, numbered 337 to 342, all remarkable for the apparently complete absence of affectation both in the sitters and the treatment generally. The second prize in Class 1 was decreed to Mr. Crawshay, whose gamekeeper's head (332) is a powerful work, worthy of the honour. Retaining this, the giver of the prize waives his claim to the substantial outward evidence, which passes into the worthy hands of Messrs. H. P. Robinson and N. K. Cherrill, of Tunbridge Wells. These thoroughly able artists have the second 25l. prize in the first class, and the first 25l. in the second class. The 25l. for best enlargement goes to Mr. C. Ferranti, of Liverpool, exhibitor of Nos. 317-320, four enlarged photographs. Among the competitors in this class we find the accomplished Mrs. Julia Cameron, a popular artist of the first rank, esteemed almost as an artistic prophetess by a large section of tasteful society. W. Street (of Waterford), W. Neilson (of Edinburgh), Vandyke and Brown (of Liverpool), B. J. Edwards (of Hackney), the Woodbury Company, of Hereford Lodge (Brompton), and Mr. John S. Palmer (of Stonehouse), with an extremely pleasing collodion transfer on toned paper from a small untouched negative, are all found among the runners, and, in sporting phrase, deserve places.

In the Crawshay Landscape Stakes Messrs. Robinson and Cherrill again carry much, if not all, before them. Their three exquisite productions, Nos. 276, 277, and 288, severally entitled "Repose," "Under the Greenwood Tree," and "Declining Day," prove that neither the taste nor the skill have waned that presided years ago over "Bringing Home the May," and subsequently over "The Willow Tree Aslant the Brook." By the gift of intelligent selection of subjects, coupled with a happy combination of parts and skilful handling, these gentlemen succeed in obtaining effects hardly to be expected by outsiders or to be rivalled by professionals.

The second prize, "for any landscape," was hard to win among so many able starters; but as more than one could not have it, No. 286, one of several splendid examples of Welsh scenery, by W. D. Sanderson, of Deansgate, Manchester, was pronounced the winner, and worthily deserved it. "La Ville d'Eu" (293), in the immediate neighbourhood of the constellation

above referred to, was printed as long ago as 1869 by Mr. Sydney Smyth, and is a beautiful work. There is a weird solemnity perfectly riveting about J. Brier's "Pandy Mill" (302), and Mr. Henry Piper's foreshore effects from the wild coast of York and Durham (306) are as happy and original achievements as can be imagined within the present known domains of photography. Among the as yet undecorated competitors, whose claims on various grounds may have somewhat puzzled the judges, are many pleasing and romantic subjects. Such, for example, are the "Berwickshire Glen" (253), by G. Bruce; an enlargement of a very popular mill subject among Devonian rocks, by Mr. B. J. Edwards, of Hackney; a delicate morsel or two at Goring, and on the beautiful river Cherwell, near Oxford, by J. Vaughan (268 and 269); and a "Lock on the Avon" (272), by the same tasteful hand.

Having dealt to the best of our ability with the prizemen, we may now notice some of the more prominent of the non-competitors, to whose works the fall of day permitted us to give some measure of attention. The frame No. 1 displays six "photographs finished by the process" of Mr. H. Vander Weyde, the process being apparently a very pleasing and successful application of chalk with occasional Indian ink, somewhat in the familiar manner of Mr. Frederick Piercy, who has for some years had repute as an able adapter of photography to portraiture. Next to these, but yet unnumbered, appeared a series of twelve telling copies of marbles from the International Exhibition by Mr. W. England, we presume a member of this society's council; also a frame of clever "scraps of expression," without pretence of decorative make-up, by O. G. Rejlander. Next follow Nos. 7 to 14, eight of Valentine Blanchard's recent triumphs, including faithful likenesses of such public men as Messrs. Dillon, Croker, Manville, Fen, and Barry Sullivan. The permanence of modern photographs from the studios of our leading men seems now fairly enough ensured to guarantee to those of Mr. Blanchard, and it may be others, the future dignity and estimation of family portraits. Our artist has here a number of other specimens of his excellent quality, which it were needless to particularize. We now come to a very long series of permanent works called "autotype plain enlargements," by Messrs. Spencer, Sawyer, Bird and Co., of 36, Rathbone Place, after small negatives taken from a great variety of original subjects by different hands. The landscape study of a cottage *ornee*, near Cookham, nestling among the piled-up woods that fringe the river bank, is a delightful *souvenir* of a well-known and well-loved locality. The firm also exhibits two very fine and large tree studies from other localities, and a magnificent Chinese "joss-house," or temple, from a negative taken on the spot by J. Thomson, Esq., F.G.S. These three studies are at the south end of the principal room, and are an imposing feature of the exhibition. The same exhibitors, again, show autotype prints, on both panel and canvas, to be used as permanent bases for colour; selections from Turner's famous *liber studiorum*, printed autotypes of machinery, engravings, and other objects; all valuable aids to what may be termed "trade photography." The small study by Hugo Theile (52) of an admirably dressed child artistically posed in an arm-chair is clever enough to arrest attention *en route* towards Vernon Heath's collection, of which the "Ben Venne" (63) and "Waterfall" (74) seem to be the masterpieces. This eminent artist is fully represented also in other parts of the rooms, but does not enter himself in the competitions. Mr. Edmund Smith, of Leamington, in No. 68, "The Spring," and others, indicates successfully a loving regard for the manner of the Tunbridge experts. M. Boucher and Signor Lombardi, of Brighton, exhibit captivating recollections of Brightonesque portrait subjects; it were hard if they could not find stimulus to exertion in the fair and young of a locality where purity of atmosphere also lends its best assistance to the work. The heads of Sir R. W. Carden also are among the most felicitous of the latter artist's flights. The "Caernarvon Castle" and "Low Water" (97 and 99), by Colonel Stuart Wortley, both done by his "New Dry Uranium Method," are splendid pieces of nature. The term can hardly be applied, perhaps, to the grand pile of the building, but it may be to the characteristic foreshore. One is disposed to return to them again and again—they are so very natural. The frame No. 107 is important, from a business point of view, as containing impressions from valuable prints, printed by the Woodbury Permanent Mechanical Process, at their Hereford Lodge Works. To this complexion has photography come at last, and so has Sol himself been harnessed to the Muse's car. In our haste, we have omitted the beautiful "Autumn Sunset" (117), a fine study by F. M. Sutcliffe. "Buy My Caller Herrin," and

"Do You Think So?" (164 and 165), studies by H. G. Cocking, of Peckham, are most attractive; and quite as much can be said of four studies from the Woodland (170) by Mr. E. Fox, of Brighton. Messrs. Mayall and Co. contribute a fine series of large portraits (178-180), comprising Dr. Pritchard, Dr. Benson, J. A. Spencer, Esq., Miss Leith Hay, and Madame Patti. Mrs. Cameron's works, as usual, claim attention by their peculiar characteristics, and we find many of her pieces more comprehensible than ever by common folk, and therefore more welcome. The "Lady Hood and Children" (181), Miss Bateman (182 and 203), and King Henry (205) are not too deeply immersed in mysticism to have their charms unnecessarily obscured. J. Werge has sent, under the name of "The Children's Portrait Company," a number of very pretty portrait studies of nude children, sparsely draped, but not indelicate—a new and interesting idea, at all events, to the general public. The Woodbury Company's illustrations to Messrs. Nasmyth and Carpenter's work on the Moon (135) are, like all lunar photographs, awfully suggestive of a huge volcano-land. But we must here bring our remarks to an end by recommending an attentive perusal of the large transfer collodion enlargement (132) by Jabez and Alfred Hughes, of Ryde, of a painting of a lion's head, by Sir Edwin Landseer. The original is in the possession of the Queen, and is probably not the worst specimen of the master known. The transcript in Suffolk Street will be found a leading feature of the exhibition. We have left her Majesty and her treasure to the last, so who can find fault if he is unnoticed now for want of room?

(DAILY NEWS, October 14th.)

Last night the new session of this society commenced its operations by the usual exhibition of photographs, which was held this year in the Suffolk Street Gallery. The society does not seem to have suffered by the change of locality or the change in the time of meeting, which has also been altered from November to October. Although the rooms of the Society of Artists, where the soiree was held, are very spacious, they were not more than sufficient to accommodate the numerous specimens of photography which had been sent in, nor could the President of the Society, Mr. Spiller, find fault with the number of visitors who attended on this the 19th anniversary of the Exhibition. There were altogether 466 exhibits, besides miscellaneous specimens, displayed on the central tables, containing an album of portrait enlargements (Crawshay Competition), by Carlo Ponti; transparencies of sculptures in the Albert Memorial Chapel, by the Misses Davison, &c. The Exhibition consisted, as usual, of portraits, landscapes of celebrated localities, sketches of nature, animals, plants, and curiosities. It would be quite impossible to do anything like justice in detail to the merits of the artists where all can pretend to some degree of excellence, for it is certain that without that attribute the pictures would not find a place on the walls of the society. Mr. Robert Crawshay has continued his gift of prizes for enlarged landscapes and portraits this year, and these represent a very notable section of the Exhibition. There is also a large series of views from New Zealand, India, and the Asturias. The contributions of Spencer, Sawyer, Bird, and Co., are also numerous, and will attract notice. Messrs. J. E. Mayall and Co. send some excellent portraits. Lieut.-Col. Dixon has various representations of scenes and places of interest in India, and Lieut.-Col. Roche of places of interest and beauty nearer home. There are some excellent exhibits by Ferranti, Lombardi, Valentine Blanchard, &c. But, as we have said, it is impossible to mention all. There are three contributions, however, by Mons. L. Bertin, Nos. 93, 207, and 213—all figures—which deserve notice for the vigour and judgment of their execution. There are but few instantaneous views and dry-plate subjects, but there are some examples of the earliest preserved plates. There are numerous representations of the mechanical printing processes, and some enamels. The exhibition will remain open till Wednesday, the 5th of November, from ten a.m. till dusk, and on Monday and Saturday evenings from seven till ten.

#### THE ACTION OF RAYS OF DIFFERENT REFRACTIBILITY UPON THE IODIDE AND BROMIDE OF SILVER: THE INFLUENCE OF COLOURING MATTERS.

BY M. EDMOND BECQUEREL.\*

It is known that the physical condition of substances sensitive to light, as also the presence of bodies which aid in the chemical action, and are principally of an organic

nature, will not only augment their sensitiveness, but may also vary the portion of the luminous spectrum by which they are impressed. In this respect iodide of silver is a body which gives the most decided results. If this compound is prepared, as in the Daguerreotype process, upon a plate of silver, and exposed to the action of the solar spectrum without having been previously impressed by light, it is only sensitive from the blue to the extremity of the ultra-violet: that is to say, that the limit of the chemical action on the least refrangible side is found between F and G, and the maximum action between G and H, near to G. But, as I have already shown in 1840, if the iodide of silver has been first of all insolated for a very short time before it is exposed to the action of the spectrum, then not only is it sensitive between the preceding limits, but it becomes also impressionable between the red and the blue, with a second maximum of action situated near D, the intensity of action depending upon the degree of insolation to which it has been subjected. This is a remarkable instance of change in the zone of sensitiveness, which is due solely to the purely physical modification to which it has been subjected.

At the same time this effect of the red and yellow rays takes place, under certain conditions, without having recourse to the action of mercurial vapour; and if you examine, after a certain period, the effect produced upon an iodised silver plate, it will be seen that the reduction of the silver gives a trace of matt white in this prismatic region, stretching even a little beyond the visible red, while the same effect produced in the blue and violet only presents a trace of black, a proof of a physical state different to the reduced silver. Use has been made of this property of yellow and red light in rendering images apparent upon iodised plates of silver, without mercury, by the sole action of light.

Iodised Daguerreotype plates exposed to chlorine or bromine, and, after a preliminary insolation, exposed to the action of the spectrum for a short time, will also present in the red, and even beyond, results different to those which ordinary light produces; but if the exposure to the spectrum is of very long duration the effect is not so obvious. But with or without the aid of mercury vapour, there is to be seen in the yellow and red, and even beyond, the reduction of silver of a whitish tint, different to that afforded by the violet rays.

If iodide of silver is obtained by double precipitation, and fixed upon paper or incorporated in collodion or gelatine, the effects observed may be different according to the conditions of the luminous action. When precipitated and in a pure state, we know that it is very nearly inactive; fixed upon paper, and in presence of an excess of nitrate of silver, which aids the decomposing action of the light, it becomes very sensitive, and, without the employment of the developer, it shows the results of continuing rays and two maxima of sensitiveness, the one in the yellow, and the other in the blue violet. Bromide and chloride of silver behave in the same way.

If the iodide of silver is incorporated in the collodion, and constitute a sensitive film such as is used in photography, and if, insolated or not insolated previously, it is exposed in a moist state to the solar spectrum for a sufficiently brief period, and developed either by protosulphate of iron or pyrogallie acid, you observe only an action extending from the ultra-violet to between F and G, with a maximum of action between G and H, near to G. Chloride of silver behaves in the same manner, but bromide gives under these circumstances a little longer impression, reaching to green. The influence of this preliminary insolation is not seen upon a wet collodion plate except under conditions which have not yet been definitely fixed upon. But if you work with dry collodion films, you may obtain the same effects as with plates and papers under the conditions referred to above, and by giving the plates a preliminary insolation, secure impressions of the less refrangible rays of the spectrum.

\* *Comptes Rendus.*

Dr. Vogel observed some time ago the curious fact that if there is mixed with bromised or iodised collodion different colouring matters, the span of the sensitive zone in the spectrum may be altered, and the surface may become at once impressionable to the red, yellow, and green rays, according to the nature of the substance in admixture with the collodion; so that the collodion surface becomes sensitive to rays which, before the introduction of the colouring matter, had no influence. Among the colouring matters which may be cited are coralline, aniline, green, &c. By employing coralline there is an extension of the spectrum image as far as orange, with a minimum of action in the least refrangible rays between D and E in the green.

How does the colouring matter act? is the question. Does it merely act, by its presence, in aiding the reducing action of the light, and rendering the silver salt sensitive to the action of other rays besides the blue and the violet, or does it act like a screen surrounding the compound? or, as Dr. Vogel imagines, do the rays absorbed by the colouring matter mixed with the iodide become active by reason of this absorption? In the last case, we must ask how can the iodide of silver be affected by an absorbent action which goes on outside it? It is difficult to understand this first of all, or, rather, to admit that the colouring matter adhering to the iodide gets close enough in connection with it to transmit to it its special absorbing power for certain parts of the spectrum.

I believe that these results have some connection with those obtained by me several years ago, to which I have just alluded, and for this reason I desired to renew my observations. In this, M. Deshayes, of the *Conservatoire des Arts et Metiers*, came to my aid, and the careful manner in which the experiments were conducted may be estimated by the results presented to the Academy of Sciences. M. Deshayes has been enabled to reproduce some of the results obtained by Dr. Vogel with several colouring bodies, and notably has been enabled to repeat successfully the obtaining of the yellow and red rays of the spectrum without any preliminary insolation, with the aid of iodized and bromized collodion mixed with coralline.

In operating with chlorophyll mixed with collodion, a result was obtained which deserves mention. The action of the spectrum upon wet or dry collodion prepared with iodide or bromide of silver and mixed with chlorophyll (having but a slight greenish tint) gave an image of the spectrum much more extensive than that observed where there is no colouring matter in the collodion. The limits of the action which appeared after a short exposure to the spectrum was from the ultra-violet to beyond E in the green, whilst the picture of the spectrum is much more limited, as I have described above, when no chlorophyll is present. Moreover, a more prolonged action of the spectrum gave, after development with pyrogallie acid, and intensifying, a weaker impression, but a very clear one, from E to a little beyond B in the red, with this remarkable peculiarity that there was a vigorous band between the rays C and D, with these lines at the extremity. On examining carefully the impression of the spectrum, a second band, rather less vigorous, or a second maximum, beside the less refrangible one, was to be seen, and again, fainter bands in the green; so that the portion EB showed several active bands, and in the interval were several minima of action; but what was most remarkable was, that the first active band CB was much more vigorous than the others.

This result was obtained in all cases, and with different proportions of chlorophyll. As the action of this active band CB is less vigorous than that of the violet portions of the spectrum, it will be necessary, when the effects of both portions of the spectrum are required on one and the same surface of equal intensity, to let the red act upon the film five or ten times as long as the violet.

In one case only was a different result produced upon a film which had received preliminary insolation. In place of the active band CB there was an absorption band; but

as the action appeared similarly reversed in the middle of the region CH, it is possible that this plate turned out, accidentally, a positive instead of a negative.

If you examine by means of a spectroscope the bands of absorption in a solution of chlorophyll, you see, according to the concentration and condition of the solution, that the bands vary in breadth and position. There are two to be found in the red and the orange, and the least refrangible, which has been called the characteristic band of the chlorophyll, preserves, in general, the same place, and has the same dimensions, as those of the active band upon the sensitive collodion mixed with chlorophyll—in other words, the lines B and C of the solar spectrum. Of this I was able to assure myself by means of a certain bulk of collodion which had served me for my experiments. The first absorption bands of the chlorophyll appear, therefore, to correspond to the active bands of the sensitive film, in accordance with Dr. Vogel's experiences with other colouring matters.

It behoves me to remark, moreover, that chlorophyll is a phosphorescent substance, and it is well known that the light emitted by virtue of the nature of the substance is in great measure composed of red and orange rays, whose limits of refrangibility correspond equally to the limits of the first absorption band. It may be said that the light that is chemically active upon collodion mixed with chlorophyll is the light of phosphorescence, for this is principally given by the other rays of the spectrum than those comprised between B and C, and the method of experimenting completely divides the active portions from one another. This coincidence should be mentioned here, because, in the photographic image, as in the emission of ordinary light, the part BC has an intensity much superior to that of other active bands of the less refrangible portion of the spectrum.

Thus, as I have already said, the action observed in the less refrangible rays of the spectrum upon salts of silver surrounded by chlorophyll can scarcely be attributed to an absorption of rays by this matter acting as a screen in the ordinary way, for such absorption would be exercised by the colouring matter itself outside the silver compound. The effect ought, indeed, to be the reverse of that obtained. We must, therefore, suppose that the colouring matter adhering to the sensitive compound, although in the shape of a very thin film, forms one substance with it, and transmits to it the action of light upon it. The sensitive compound then acquires the absorbent properties of the substance fixed upon it.

If this is not the case, the chlorophyll acts simply like other organic bodies, rendering the haloid compounds of silver sensitive to the action of the less refrangible rays, and there would be but a simple coincidence in the positions of maxima of action and the maxima absorption of the colouring matter when this acts as an absorbing screen. This coincidence may exist just as well as that of the position of several maxima of absorption with the position of maxima of intensity of the spectrum by emission of phosphorescence, or by the action of the substance itself. The phenomena of luminous absorption are so little known that reasons for their existence can scarcely be given, but the hypothesis I have cited seems more in harmony with the results obtained.

Whatever may be the explanation of this matter, however, the action of a colouring substance in a very thin state, enveloping a sensitive chemical compound, shows that perhaps substances preliminarily insolated, such as the iodide, bromide, and chloride, do not become sensitive to the action of the less refrangible rays except by a change in the colour or state of their surface, the absorbent power of the surface, for the different rays of the spectrum, being then changed. In this way we should take into account the continuing rays, whose existence I pointed out some time ago. By a similar action going on in different parts of a plant, the luminous action may be modified by the presence of substances—chlorophyll, or other colouring matters—such as are found around and in the interior of its cells.

### LAMBERT-TYPE: A METHOD OF ENLARGING AND FINISHING NEGATIVES.

THE method of enlarging and finishing negatives known as Lambert-type has, for some months past, been exciting considerable interest amongst French photographers, as our readers have already learned from the letters of our esteemed Paris correspondent, Mons. Lacan. During a recent visit to Paris we were favoured by Mons. Lambert, the inventor and patentee, with full opportunities of witnessing his operations in all their details. We may remark, before proceeding to details, that M. Lambert is a photographer of great intelligence and enthusiasm, and one of the most facile and perfectly skilled manipulators we have ever seen. He has been engaged for some time in enlarging for the profession, and the method now under consideration is, he states, the result of five years' experiment in this direction. The protection by patent was, we were informed, an after-thought, the result of some unfair practice in relation to the process of some one with whom the inventor had business relations. The process having been patented, Mons. Liebert, a skilful and well-known Parisian photographer, with a shrewd knowledge of business, has undertaken to aid in introducing the process to the photographers of the world. The two examples now exhibited in Suffolk Street will enable photographers better to judge of the results than many pages of comment.

We shall proceed to describe the operations as they came under our attention, some, of course, being already familiar to English photographers who have given attention to enlargement. Any negative is accepted for enlargement, and the better the quality the better the result; but no attempt is made to retouch or improve the small negative, nor is any retouching attempted on the transparency. The latter is produced on a suitable carbon tissue, the special characteristic of which seemed to be a thick layer of gelatine with very little colour. From the carbon transparency an enlarged negative is produced in the usual manner on wet collodion, with iron developer. And here we noticed the first special peculiarity of Mons. Lambert's method of working. Instead of aiming to produce a negative with any approach to printing vigour, his object was to produce a thin delicate image full of detail, but with little contrast and scarcely any density. The iron solution was flooded freely over the plate, washing over the edges much of the free nitrate on its surface. The result rather resembled an ordinary collodion positive than a negative, and no attempt was made to intensify it. "All the intensification," he remarked, "will be effected when my mode of finishing is applied." This thin delicate image is fixed and varnished, and is then ready for finishing.

The process of finishing is commenced by attaching to each side of the negative a sheet of transparent paper. This has been described as *papier vegetal*. This, Mons. Liebert incidentally remarked, was an error; it was, in truth, a *papier mineral*. On this point we can only give description, as the paper is, we understand, expressly made for the purpose. It is a very thin, very tough, very transparent paper of fine texture. It is almost as thin as tissue paper, but it is much more tough; it is as transparent as tracing paper, but is free from oil, turpentine, varnish, or any fatty body which might interfere with pencil working on its surface; it is very smooth and fine in texture, but at the same time presents a free tooth to blacklead. Paper known to English stationers as bank-post, very heavily rolled to make it thinner and more transparent, would produce the nearest approach that we know of to the paper used. A sheet of this paper is attached by an edging of gum to each side (that is, back and front) of the thin negative we have described. This process alone seems to the eye to have materially added to the intensity of the negative; but as the additional thickness is equally applied over shadows as well as lights, not much practical or printing addition is gained; although, as experience has proved, a little is really gained by this operation. But the process of intensification is in reality to begin. It is effected by working on the paper at the back of the negative with powdered blacklead and a stump, the work being broad and comparatively rough; the softening effect of every touch printing through the thickness of the glass being kept in mind. Hence broad effects of light and shade are only considered when touching on this side of the negative. Next comes the work on the film side, and this is effected with a blacklead pencil, the softening effect of the stump being employed wherever it is necessary. Working freely on paper, sharp touches or soft touches can be easily secured at will, and erasure or modification with india-rubber is not impossible. Certain it is that the work is easy and rapid, a life-size negative being completely finished—defects removed, intensity added, and general softness and finish conferred—by the application of little more than an hour's labour. The results, when completed, are always good, often charming, and they are, we must confess, surprising, as the means seem so inadequate to the result. Mons. Lambert is eloquent and enthusiastic in describing the peculiar value of the two semi-transparent, or semi-opaque, surfaces of paper upon which the touching is effected in breaking up and diffusing the rays of light as they traverse the negative, and so giving a softened effect to every touch, suggestive of much laborious work from a skilled artist. There undoubtedly is the result, and there are the comparatively rough, and positively simple and facile, means by which the fine result is produced before us, and we cannot gainsay the theory.

By this time it has struck many readers that covering negatives partially or wholly with tissue or tracing paper, and working on that paper both lead pencil and powdered blacklead and a stump, are practices not unknown, and which have not been practised without record in this country. Mr. Bedford, in our YEAR-BOOK for 1868, described the value of tracing-paper so used in improving landscape negatives. Mr. Robinson and Mr. England have also practised and described similar methods. Mr. Blanchard and others have also described the advantages of applying yellow pigments to the back of the plate, and the general principle of modifying negatives by various forms of this kind of treatment has been generally known and widely practised. As to the points of novelty claimed by Mons. Lambert, and specified in his patent, we are not at present informed, as we have not seen the specification of his patent, and we did not dream of stopping the current of a courteously communicative gentleman's explanations by discussing the question of the strict novelty of every operation. But it struck us that the systematic reliance on this method of treatment for all intensification and finish is a specific novelty. It is not a method of

modifying a negative by the application of a little tracing-paper here and there, or the touching or masking partially at the back, partially at the front, which is adopted; but a systematic reliance upon a definite system of work: that is, the application of two sheets of paper, the application of intensity at the back and of finish at the front, and the securing by this combination of means a fine result, highly finished, but flesh-like, by the expenditure of less labour and less time than we have hitherto seen.

We have referred to M. Lambert's skill and ingenuity in manipulation, and we may take occasion shortly to describe various little contrivances of value which we saw in his establishment. But we must especially refer to his method of replacing an imperfect background in a portrait by printing in any other which may be desired. It is, in effect, similar to a method of double printing which Mr. Robinson has described more than once in our pages, but most ingeniously effected. Mr. Robinson has described the method of *vignetting* the two portions of different negatives to be joined into each other. This is, in effect, the method employed by M. Lambert. The enlargement of two children in the present exhibition in Suffolk Street is an example. The original background was imperfect and unsuitable. A mask of yellow paper was roughly cut to the outline of the figures, therefore, and placed outside the glass of the printing frame. A small hog-hair tool was then dipped in a little Indian red oil colour, and a graduated edging of about one-third of an inch broad round the outside of the cut-out edge of the mask, slightly overlapping the edge of the figures. Where soft draperies or flowing hair almost receded into the background, this was done softly; where the edge was sharply defined, the edging was more crisply applied. We should here explain that M. Lambert prints in a circumscribed space, surrounded by high houses, so that he prints, practically, with a vertical light; and where the situation does not naturally afford a similar light, he recommends using a box, or some similar method of cutting off the extreme lateral rays in printing. This vertical light is of essential service in the process we are describing. The imperfect background was got rid of without any trace of masking round the figures. But it was not simply to the mode of finishing the edges of the mask which M. Lambert attributed the results, but to the series of means by which the light was broken up and diffused round the edges. There was the edge of the mask and of the paint passing through the thickness of the glass of the printing frame, and then the two thicknesses of paper and one of glass through which the light again passed before reaching the sensitive surface. A background negative with a piece of woodland scenery from nature being selected for the children's figures was printed in by the aid of a similar plan of masking and softening the edges. As this negative was sharp, and might thus give the background too pronounced or advancing a character, when it was about half printed M. Lambert deliberately moved the position of the print slightly, so as to partially double the image, and, by destroying its extreme sharpness, send it back considerably, adding much to the value of the effect. The results of the operations we have described are, as we have said, now hanging in Suffolk Street, and our readers will be in a position to form some idea of the character of the *procede Lambert*, should it come under their attention as a matter of business.

## THE PHOTOGRAPHIC EXHIBITION.

### LANDSCAPES.

THERE is much fine landscape work in the exhibition now open in Suffolk Street; but, with the exception of the Auto-type enlargements, there is nothing of similar important dimensions to those we have been taught, of recent years, to look for from Mr. Earl. Col. Stuart Wortley exhibits three very fine landscapes of large size, produced direct, about twenty by sixteen inches, as examples of the work of

uranium dry plates, of the excellence of which they are admirable examples. "The Hill-side" (98), a circular picture, and "On the Seivout River, Low Water" (99) please us best." "Caernarvon Castle (97), in many respects a fine picture, is, we think, spoiled by the clouds of the printed-in sky apparently enveloping the turrets of the castle. The clouds are also too pronounced, and spoil the composition of the picture. There are also some fine examples of large landscape work by Messrs. Bool, Messrs. Hudson and Purnell, and Mr. Sanderson in the Crawshaw lists, to which we shall presently refer.

A dozen 12 by 10 landscapes exhibited by Mr. W. Bedford comprise some of the finest landscapes in the exhibition, all the excellent traditions of Mr. Francis Bedford's work being maintained in that of his son. Especially beautiful is the rendering of water in the river and lake scenes, and the perfection of atmosphere in every picture. A scene on the River Glaslyn, a view of Dina's Lake, a scene on the Dwryd, and a river scene at Aberglaslyn, especially charm us, and a rendering of hoar frost is unusually fine; but the whole series admirably joins the perfection of technical photography with fine artistic feeling in composition and light and shade. Mr. F. M. Sutcliffe exhibits a goodly number of very fine small landscapes. The size is generally about 7 by 5, but there is enough in each to form a subject. For instance, in 41 and 42 we have "Tired of Waiting," a pretty landscape with a well-placed figure at a stile; and "a Gleam of Sunshine." The former is the most effective picture. Again, in 67, we have "Hay Time," one of the prettiest pictures in the exhibition; some other good pictures by the same artist possess similar characteristics. Mr. F. Howard exhibits some fine small landscapes, a trifle of under-exposure slightly marring one or two of the forest scenes. Mr. F. Beasley contributes somewhat largely to the landscape department, his work being, we believe, by the Fothergill process, of which he has retained a faithful exponent, always producing good work. Mr. Dew has some good effects in the charming neighbourhood of Leamington. Two frames of views, by Sir Thomas Parkyns, contain some very interesting and excellent pictures. Mr. Vernon Heath contributes largely this year, his pictures being marked "Not for competition." The same neatness, softness, and fullness of detail which have generally characterized his work are present here; but there is a lack of pictorial inspiration. As a rule, the photography is, as photography, faultless, and in 72, "Maenturog from the Garden," there is something more than mechanical excellence—a piece of fine pictorial work. In Nos. 63 and 64, two views in the neighbourhood of Loech Katrine, with delicately rendered foliage, the pictorial value is spoiled by an error of taste in mounting, which we have before cautioned photographers against adopting. The oval outline of the vignettted picture is exactly followed by a mount with oval aperture. Vignetting in landscape work requires considerable taste and skill to be effective. The gradation of the edges should be free from any approach to abruptness, but soft, irregular, and spreading, whilst the subject and treatment of the picture generally should be light and sketchy. The greatest value will be given to the effect of vignetting, and compactness in the picture secured, if a square or oblong mount, considerably larger than the vignette, be placed over it. A mount with aperture little larger than the vignette, and following its outline, spoils all feeling of space.

Mr. H. Whitfield exhibits three small pictures with good qualities; No. 77, however, entitled "Summer Shade," is too heavy, black, and under-exposed for its title, as such shade should have space and transparency. Mr. Gale's reminiscences of rambles with the Field Clubs contain many charming little bits. Mr. J. Bowen's views of the Baptist College, Regent's Park, contain some very admirable interiors. Mr. H. Paget Swaine's views, produced on Liverpool dry plates, are in no wise inferior to high-class

wet work, and are very excellent pictures. "Mosaics in the Albert Memorial Chapel" at Windsor are fine photography, and display the good taste always present in the works of the Misses Davidson. Col. Roche sends several contributions, all good. His "Tintern Abbey" (112) is very fine, and some of the Swiss and Killarney views are excellent. Some good landscapes are exhibited by Mr. Pendryl Hall, his view of "Conway Castle from the Island" pleasing us best. A fraue of London views of various size, examples, we presume, each of a different series, exhibited by Mr. F. York, are very capital, and far exceed in excellence and pictorial treatment the usual average of street views. Some views and interiors exhibited by Mr. E. Fox possess good qualities, but are a little wanting in force and relief, delicacy being carried to excess; whilst adjoining them some pictures of a similar class by Mr. Dunmore err in the opposite direction, being spotty and confused from under-exposure. Messrs. McAndrew and Stenning send a large and interesting series of Spanish views from the province of Asturias, containing some very fine picturesque work, the skies being in many cases printed in. In one case, however, it seems to us that an effect much in exaggeration of nature is produced, where the clouds seen underneath the arch of a bridge gave the latter an appearance of magnitude equal to that of a huge mountain. Speaking of clouds reminds us of the clever cloud studies of Mr. J. C. Stodart, of Margate. The same gentleman's four large instantaneous views of Margate (385-388) far surpass, in photographic and pictorial excellence, the majority of similar works we have seen. A large number of views sent in by Mr. J. A. C. Branfill will interest experimental visitors as illustrating the qualities of various kinds of dry plates. The New Zealand views of Mr. D. L. Mundy are very beautiful and perfect in themselves, apart from any extraneous source of interest; but the peculiar difficulties under which the majority of them were produced render them especially interesting. Mr. Mundy was engaged for two or three years in producing a complete series of views of every place and thing worth photographing in New Zealand, the whole of his material, apparatus, and facilities of every kind, being transported on pack-horses the whole of this time. Much of the work is not inferior in delicacy and perfection to the best produced under the most favourable conditions. Mr. W. G. Hunter exhibits a series of very charming cabinet views, singularly delicate and picturesque, and possessing a peculiarity of tone and texture resembling prints on opal glass. Mr. G. W. Wilson, of Aberdeen, exhibits a number of his charming cabinets views of Highland scenery. Col. Dixon's large series of Indian views are very interesting. Mr. W. J. Hollebone's Swiss views on Wortley dry plates are excellent. Mr. Fernley has some good landscapes, in some of which a tendency to under-exposure should be guarded against. Mr. S. Thompson exhibits photographs of sculpture, which are exceedingly perfect. Mr. Frith sends some capital views. There are also views by Mr. Dyball, Mr. Whiting, Mr. Wray, and some others which do not call for special comment.

Turning for a moment to the landscapes competing for the Crawshay prizes, we may remark that, whilst they comprise many excellent pictures, they are scarcely equal as a whole to our expectations as competing for prizes upwards of fifty pounds. We feel some difficulty in entering into detailed comment, from the simple fact that we recognize many of them as pictures exhibited some years ago, and we have no certainty as to which are new pictures. Should a similar competition be again opened, it would be wise to make production within the year a condition of competition, as the aim is clearly to stimulate the production of good work, not merely to induce the exhibition of good work done some years ago. As no such condition was made, the competitors were clearly at liberty to send in any work they chose, and the judges were bound to award to the best work, without question as to its date. Amongst the manifestly new work, we may mention the

large pictures by A. and J. Bool: Nos. 249 and 250, river scenes, with well-placed figures, are exceedingly fine. Mr. Bruce's "Dunse Castle," "A Berwickshire Glen," and "Langton Mill Burn," are clearly new, and exceedingly fine, but perhaps a little deep in printing and black in tone for landscape work. Mr. Roger Williams and Mr. Gulliver both send some capital landscapes. Mr. Edwards's enlargements of Mr. Henry Cooper's landscape negatives give fine pictures. Messrs. Hudson and Purnell send large views from the Isle of Wight which are very excellent. Mr. Crawshay himself sends some most charming views of South Wales scenery. Few of the landscapes exhibited please us better than Mr. J. Brier's "Night at Styperson, Cheshire" (No. 300), a thoroughly poetical picture; and all Mr. Brier's landscapes are, we may add, excellent. Mr. W. Nicholson sends some very excellent examples of Isle of Wight scenery. Mr. Reuben Mitchell's views always possess picturesque qualities, and the "Threatening Storm" is especially fine. Mr. Henry Piper sends some very good work. Mr. Vaughan's views, somewhat peculiar in treatment and mounting, possess much merit. Mr. Sutcliffe and Mr. Branfill, of whose work we have already spoken, send in some good pictures for the competition. Mr. Sydney Smyth sends some fine instantaneous views which we recognize as old favourites. Of the prize pictures we have before spoken, and need not enter into detailed comment here.

Before concluding our notice this week of the exhibition, we may call attention to some very admirable photographs of spectra sent for exhibition by Mr. Norman Lockyer, F.R.S. It may interest our readers to know that the production of these photographs was chiefly the work of Mr. R. Friswell, the new secretary of the society, to whom we are indebted for the following descriptive note thereon.

"Commencing on the left hand portion of the spectrum of barium, near G, an example of the method of obtaining registers of the lengths of the metallic lines. The spectrum here represents a section of the light taken at right angles to the axis of the poles at a point about midway between them. We have here a demonstration of the observation first made with the eye on a less refrangible part of the spectrum, *i.e.*, that the ignited vapours lying between the poles consist of a dense core through which the principal discharge takes place, surrounded by numerous layers of vapour, becoming less and less dense as they recede from the axis of the discharge.

"In the core itself we have an approach to the effects obtained by Frankland in his celebrated researches on the cause of the illuminating power of flames, the gases being sufficiently dense to give, in many cases, a continuous spectrum. As the core is receded from, the gases become less dense, and the lines fewer in number. These lines, which are produced by the most tenuous vapours, are those which are reversed in the solar spectrum. In the next photograph we have the spectrum of the Lenarto meteorite (in which Graham discovered occluded hydrogen) compared with the spectra of calcium and aluminium. The three photographs were taken in succession on the same plate, a sliding shutter with a square hole placed in front of the slit uncovering the portions of the plate in succession.

"The next example is the solar spectrum compared with the spectra of calcium and barium. The calcium exhibits, in the very thick line near the centre, a remarkable example of the power possessed by a very dense but comparatively cool gas, of reversing itself—*i.e.*, of absorbing the light given out by the hotter interior portions of itself. In this photograph the sliding shutter was also used. The coincidence of the dark solar lines with the bright lines of the metals is very distinctly rendered. The last photograph is one of the same nature as the first, the metal being iron. It is enlarged to a greater extent, and one half of the total length of lines only shown.

"All these have been enlarged from plates in which the actual available portion of the spectrum did not exceed two inches in length. On account of the enormous dispersion, the portion of the spectrum in focus at one time is very small. The focus was obtained by the removal of the focussing screen, and the use of a negative eye-piece in the first instance; the final adjustment being obtained by a laborious system of trial plates, as no other method was available in this highly refracted portion of the spectrum."

**TWO REASONS WHY PHOTOGRAPHS BECOME YELLOW.**

OUR readers will remember that nearly two years ago, Dr. Gayer, in a paper read before the Photographic Society on the causes of fading in silver prints, insisted on the importance, as a condition of permanency, of fixing in the dark. In a recent issue of the *Photographische Correspondenz*, Herr Fritz Haugk, apparently unfamiliar with Dr. Gayer's paper, insists on a similar condition as the result of independent observation. He says:

"All photographers know very well that pictures toned in the open daylight always have a grey and dirty appearance afterwards. But it is not so generally known that in the fixing process a bright light is also to be avoided, and in proof of this I may mention a circumstance which has recently come under my experience.

"Some time ago I fixed, about the middle of the day, several dozen pictures, which were destined for my own album. During the operation I was called away for a few minutes, and during this time I left the pictures in the fixing trough in the yard, when the operation was completed, not in sunlight, however. All these pictures are now as yellow as lemons, while pictures which I had fixed days before and days after, for the same purpose, still retain their original whiteness. An accidental defect in the washing of these pictures cannot be the reason for the yellowness in question, as I always test most carefully the last washing water with Vogel's iodine preparation, and rinse three times after this.

"Another reason why pictures discolour rapidly is the following.

"I had prepared some pictures which were also intended for my album, and after mounting, put them on one side under pressure of some books. In this way they remained forgotten for about twenty-four hours. These pictures, I find, also show, all of them, a light yellow tint, while other pictures produced about the same time show no trace whatever of defect.

"From this it would appear, therefore, that photographs should be dried as soon as possible after mounting, for it is the keeping of them moist for a long time that is the cause of the yellowness in the specimens referred to."

**COMBINATION PRINTING.**

BY GEORGE BRUCE.

AN easy system of combination printing is one of the things which must necessarily be of great interest to the photographic profession, for were the manipulations connected with this plan of making pictures made more easy, greater efforts would be directed to their production.

As one of those who do a little in the way of combination printing, I have read with considerable interest the answers given to the challenge made, through your advertising columns, by Mr. Tilley regarding his method of combination printing without the use of cut-masks. So far Mr. Tilley is master of the field, and very justly uses the right of a champion to throw down his glove in face of the whole fraternity, for a secret must always give the happy possessor of it a feeling of importance above his fellows, even though it should not add to the weight of his purse. There is a natural craving in men to know the unknown, and if there be a profession likely to intensify this craving more than another, it is that which we follow.

Here, then, we have a mystery—a secret—fitted to excite the curiosity of all who love and practise photography, which is well worth unfolding, if it be as valuable as Mr. Tilley proclaims it to be. That gentleman has given us a chance of "cracking the nut" and solving the mystery within a given time, with the understanding that should any one be fortunate enough to stumble on his method we shall save our money, while he will be minus the cost of his advertisements.

With these prefatory remarks, I beg to lay before your readers a method for making a perfect mask without the application of scissors, presuming that if it be not Mr. Tilley's plan, then, perhaps, it may be mine, as I do not remember having seen it described before.

Take your figure against a white background, or, if the negative be already made, with a dark background; then paint it out up to the edge of the figure all round. Take a very deeply printed impression from this negative, which, of course, will be all white paper except the figure. Without toning, fix this print. Then wash, and float for a minute or two on a solution of—

Chloride of sodium	...	...	5 drachms
Citric acid	...	...	4 grains
Distilled water	...	...	19 ounces

When the print is dry, it is ready for the next operation, which is very simple.

With a brush dipped in a strong solution of silver, paint over those parts of the figure that are white—such as face, hands, &c., or white parts of the dress—and expose it to the light till all is black; wash the print for a few minutes to free it from the salting solution, and, when dry, wax the print to make it transparent.

You have now a most perfect mask, covering the figure even to the hairs, the only drawback to its use being that the landscape background must be printed through the paper on which the mask is printed. *Papier vegetal* can be used instead of albumenized paper by salting and sensitizing in the ordinary way, and then printing the figure upon its surface in the way I have described.

This system of masking may be used for giving various artistic effects to the backgrounds of our pictures without showing any join. Paper negatives of landscapes, clouds, stippling for large vignette heads, &c., may be made in the same way, and applied with great effect in the production of artistic pictures.

**NEW METHOD OF PREPARING PHOTO-LITHOGRAPHIC TRANSFERS.**

BY M. L. BORLINETTO.\*

I COVER a well cleaned plate with some oxgall, which may be preserved for a considerable period by admixture with creosote. By means of a bit of woollen cloth I rub lightly over the surface of the glass so as to cover the plate with gall as uniformly as possible, and to leave no kinds of lines. I dry by means of a mild heat, and while the plate is yet warm I put it on a levelling stand.

I next prepare a solution of gelatine, thus made up:—

Gelatine	...	...	...	5 grammes
Water	...	...	...	50 "
Alum	...	...	...	1 gramme

This is filtered thoroughly through a bit of flannel, as soon as the gelatine and alum are dissolved. While yet warm, I pour it upon the plate treated with oxgall. If the gelatine is rather troublesome in flowing, I help matters with a bit of cardboard. I then take a sheet of strong white paper, immerse it in a water bath, and, when thoroughly saturated, blot it on a sheet of filter paper. I then spread it upon the gelatine, taking care not to form any air-bubbles, or to let any of the gelatine get on the back; then everything is left to the morrow. If the weather be not too damp, the gelatinized paper will become detached of itself; but if this does not happen to be the case a penknife may be used for separating the paper at the margin. The surface of the sheet thus prepared is of a brilliant character, and it may be preserved for an indefinite period.

When I want to make use of it, it is plunged into a solution of bichromate of potash of three per cent. strength, and suspended to dry; it is then ready for print-

\* *Revista Fotografica.*

ing under a negative. As soon as the image appears in all its details it is plunged into a solution of—

Nitrate of silver	...	...	1 gramme
Alcohol	...	...	20 grammes
Water	...	...	50 "

The surface of the paper then becomes of a brick red, in consequence of the formation of chromate of silver. I wash in pure water, and then pour upon the image some liquid ammonia diluted with three volumes of water. Under this reaction the reddish tint disappears, for chromate of silver is soluble in ammonia, and there remains an image of a pale green, formed of oxide of chromium.

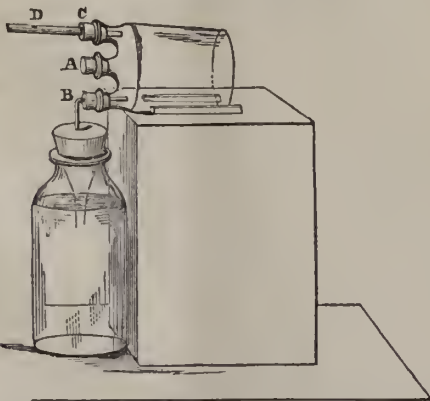

After this change I wash once more in water, and place the prints, face downwards, upon a board of hard wood (perfectly clean, of course), to which it is fastened by means of pins. This done, with a dry and very clean sponge the excess of humidity is removed from the surface, and then the print is inked with a lithographic roller.

The advantage of this process over all those with which I have hitherto experimented lies in the fact that the greasy ink attaches itself immediately to the print, even when it has been over-exposed; and that one has never reversed images to deal with, as is the case in other methods where the non-decomposed chromium salts have not been eliminated. The gelatine, by the addition of alum in the first solution, and its immersion into the bichromate of potash bath, becomes completely insoluble, and its consistence is augmented still further by the effect of the silver solution.

#### A TIDY FILTER FOR THE NITRATE BATH.

BY E. H. SPEIGHT.

On the top of a box about twelve inches high, place a three-necked Woulff's bottle. Nail two strips of wood on the box to prevent the bottle rolling off. Into neck B press a perforated cork and glass tube (tube to be bent at right angles). In neck C a perforated cork, with a piece of cane about three inches long through the perforation (see enlarged plan of cork and cane). Paint the end of cane outside the bottle at C with varnish, to stop up the pores. Make a

small cut at D. At neck A pour in the bath, and cork tightly. Arrange the bottles, box, and funnel as in diagram. Use double filter paper. The solution will now pass through tube B, faster or slower, according to the size of cut D. If cut D be found too large, paint it with starch or varnish, &c., then make a smaller cut in another place. Do not wet the cane with solution. My Woulff's bottle holds a pint.

#### Correspondence.

##### WINSTANLEY'S METHOD OF REDUCING THE CAMERA EXPOSURE.

SIR,—The time-honoured custom of recording discoveries in the anagrammatical form—a custom which was adopted by Kepler and Huyghens in reference to the physical formation of the planet Saturn, has been again revived in a recent number of your excellent contemporary *Nature*.

With your permission I beg to place on record in this manner the secret and the theory of my method of reducing the camera exposure. The translation will be given after a reasonable lapse of time.

A, B C<sub>7</sub> D<sub>3</sub> E<sub>11</sub> F<sub>6</sub> G<sub>4</sub> H<sub>6</sub> I<sub>12</sub> L<sub>2</sub> M<sub>3</sub> N<sub>7</sub> O<sub>6</sub> P<sub>2</sub> Q R<sub>3</sub> S, T<sub>13</sub> U<sub>3</sub> V X Y<sub>5</sub>.

I am yours respectfully,  
October 17th, 1874.

D. WINSTANLEY.

##### SOUTH LONDON TECHNICAL MEETING.

DEAR SIR,—I see that this meeting is to come off next Wednesday evening, and I hope that, as the meeting is free, not only the members, but other photographers also, will contribute from the stores of their experience to make the meeting thoroughly useful. I intend to send something myself of a practical nature, which I have found of advantage in daily working. I hope others will do the same, for we must all help each other. Almost every man works out something that he feels is in advance on what is in general use, and such a meeting permits each to give and take. I am glad that the meeting, as I see by Mr. Cocking's letters, is to be confined to practical matters. It is not everybody who understands theory, but the details of practice we all know, and want to know more.

Some may show an improved dipper that will not permit the plate to slip off, a better kind of bath, a fresh mode of filtering, a new means of preserving sensitized paper, an improved cork or stopper, or a kind of developer. Speaking of this latter I see that some people have recently been recommending the omission of acetic or any acid in the developing solution. I should like to see some negatives so taken, as recently I have found the advantage of doubling the quantity of acetic acid that I formerly used.

If some of those gentlemen who have been successful in shortening the exposure in the camera by the preliminary exposure of the plate to light through opal or coloured glass, or in any other way, would show how they have done it, they will render a great service.

I see that short pithy papers are invited on practical subjects. It strikes me that such short concentrated articles as appear annually in the *YEAR-BOOK* are just the things required for this meeting. Nothing is so interesting as the results of actual practice, especially if confirmed by daily trial. Everybody is obliged to use those ingenious expedients that are disrespectfully called "dodges," and everybody knows their value, or they would not use them. Fresh examples are always occurring, and few things are more interesting to real practical men; therefore let no false shame stand in the way of exhibiting these examples of ingenuity.

One thing, in conclusion, let me impress on those who attend the meeting, but who have not contributed anything; that is, to be tolerant to those who have, and to remember in how much higher position those stand who do attempt to help and contribute, than do those who do nothing.—  
Yours, &c.,  
A MEMBER.

##### PHOTOGRAPHIC EXHIBITION FOR SCOTLAND.

SIR,—We have had no exhibition (photographic) in Scotland for a long time, and as the society has a considerable sum of money, I think some of it might be spent in

conveying the pictures now exhibiting in London to Edinburgh, if their proprietors will allow it, and have an exhibition there.

If this suggestion should be agreeable to the two societies, I have no doubt it would help to stir the photographic mind in Scotland, and gratify the eye of more than one.

Glasgow, October 19th.

OLD EXHIBITOR.

## Proceedings of Societies.

### MANCHESTER PHOTOGRAPHIC SOCIETY.

THE annual meeting of this Society was held at the Memorial Hall, on Thursday evening, the 8th instant, Mr. W. T. MABLEY, President, in the chair.

After the routine business had been disposed of, the Secretary read the

#### Annual Report.

YOUR Council, in presenting the nineteenth Annual Report, have to express their great satisfaction at the continued prosperity of the Society.

The proceedings of the past session have been more encouraging than for some years previously. The meetings have not only been more numerous attended, but also more instructively occupied.

It is very gratifying to your Council to be in a position to report a small increase in the number of members. There are seventy-six against seventy at this time last year. The average attendance at the meetings has been thirty-one and a-half against twenty-seven.

Several papers have been read, and other matters of interest have been contributed. For instance:—

Mr. Wade gave an illustration of carbon printing.

Mr. A. Brothers read a paper "On the Sciopticon for Enlarging."

Mr. Noton read a paper "On the Manufacture of Lime Cylinders."

Mr. Brothers exhibited a series of photo-lithographs of the "Triumphs of Maximilian." Mr. Brothers also communicated some particulars in reference to the fading of silver prints, and exhibited some examples of a very conclusive character.

Mr. Noton read an appendix to his former paper on Limes.

Mr. J. Brier read a paper "On the Production of Enlarged Landscape Negatives."

Mr. Frankland exhibited a number of photographic conveniences.

Mr. Noton exhibited a new form of lantern for the lime light.

Mr. Pollitt read a paper "On Enlarged Negatives by the Wet Process."

The session included two lantern exhibitions. An attempt to rescintate the outdoor meetings hopelessly failed, and this once important and enjoyable part of the annual programme may be considered to have had its day.

Your Council are full of hope that the Society has yet a long and useful life before it, and they desire the active co-operation of each and every member to the end that all things may work harmoniously together; that the meetings may not only convey instruction, but give pleasure to the members; that minor difficulties may only precede major triumphs; and that peace and goodwill and mutual forbearance may crown all your efforts with well-merited success.

The annual report was accepted, and the Treasurer's accounts passed.

The election of officers for the year was then proceeded with, and resulted as follows:—*President*—Mr. W. T. Mabley. *Vice-Presidents*—Rev. Canon Beechey, M.A., Messrs. A. Brothers, F.R.A.S., T. Haywood, G. T. Lund, and M. Notou. *Council*—Messrs. Jno. Brier, Jun., W. G. Cooté, W. Hooper, I. Wade, E. Woodward, J. Warburton, N. Wright, A. Patterson, J. Pollitt, and J. Frankland. *Treasurer*—Mr. J. H. Young. *Secretary*—Mr. Chas. Adin, Clifton Bank, Wellington Road, Whalley Range, Manchester.

Mr. ROBINSON (on behalf of Messrs. Vandyke and Brown, of Liverpool) presented three autotype mechanical prints to the society.

Mr. Brothers sent several very clever photo-chromolithographs for exhibition, the work of his friend, Mr. Griggs. These were much admired.

Mr. Cooté contributed a specimen of his old enemy, marbled plates—this time by the wet process—and a print on paper that had been kept five and a-half months between sheets of blotting-paper saturated with a thirty-grain solution of carbonate of soda, and dried. The print was of fair average quality.

The Chairman read a letter from the Rev. Canon Beechey, M.A., referring to a "sub-leader" in the *British Journal*, and stating that he had sent the plates to the meeting for the inspection of the members. These plates were examined with much interest.

The thanks of the Society were accorded to Messrs. Vandyke and Brown, Mr. Brothers, and Canon Beechey, and the meeting was then adjourned.

## Talk in the Studio.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—The Annual Technical Exhibition of this Society will take place at its first meeting for the winter session on Thursday, October 29th, at seven o'clock, free admission being given to all interested. We are requested to state that the 29th (and not the 28th) is the day appointed for receiving objects for exhibition at the place of meeting, Cambridge Hall, Newman Street, Oxford Street.

**USEFUL CURTAINS.**—A good way to curtain a light, and the cheapest way considering its advantages, is by means of curtains of white muslin, from a yard to a yard and a-half wide, made to run on wires by attaching curtain rings, about six inches apart, to each side of the curtains, and, running the wires through them, stretching them taut. Put a stick the width of the curtain through a wide hem at each end. The curtains are perfectly manageable in this way, as they slide easily on the wires, and open from either end. They may be adjusted with cords properly attached, or, when lying horizontal or nearly so, by means of a long stick. A piece of bamboo cane, like those used for fishing rods, is the best, it being very light and strong. It is the method I am using in my new gallery. The spring rollers are neater, but I do not like them in practice as well.—*Philadelphia Photographer.*

**DURABLE SENSITIZED PAPER.**—(H. J. Newton).—"The preparation of a sensitized albumen paper as a commercial article has not been successful. It has been either too expensive to meet the popular demand, or deficient in keeping quality. There are several ways by which paper can be prepared so that it will keep indefinitely; but, as a rule, it is exceedingly difficult, if not impossible, to make a print on such paper that would not ruin the reputation of any photographer, especially after it is a week old. Some time since, in experimenting in this direction, I found that by floating the albumen paper, back down, for one or two minutes on a solution of hydrochloric acid (one ounce of acid to forty ounces of water), and drying, it would render it capable of keeping perfectly for ten or twelve days after sensitizing. Not only this, but the prints made on paper thus prepared were remarkably fine; and also those made after ten days' keeping were equal to those printed immediately after sensitizing. Paper so prepared should not be fumed until required for use. After the paper has been removed from the acid solution and dried, it would be well to pack it away under a light pressure, placing the albumen surfaces together, so that when required for use it will be in proper condition to put upon the sensitizing bath. As it is a great convenience for photographers to be able to keep paper for several days after sensitizing without its deteriorating, I would suggest that some of our many manufacturers of albumen paper prepare some of it in this way, as I am sure that photographers would willingly pay the extra expense. In the toning of these prints I used a little tartrate of antimony, and it worked very well. In the first place, the prints turned red—a very deep, rich colour—and toned up from that. I have not experimented enough to give a reliable formula, but I would suggest half an ounce of tartrate of antimony, which is commercially known as tartar emetic, dissolved in sixteen ounces of water. For each grain of gold, use half-a-dozen drops of that solution, and increase it until you get the desired effect."

## To Correspondents.

**ENQUIRER.** The usual rule of admission of non-members to photographic meetings is introduction by a member; but all photographers are invited to attend the technical meeting of the South London Society, and will be admitted without payment on presenting their cards.

**FOG.**—It is a good rule to keep the bath and all the chemicals, and the temperature of the operating room as well, as near to 60° Fah. as possible; but it is not wise to warm the silver bath to a higher temperature than the other solutions. The loose surface fog, as we have before said, may arise from many causes; a bath containing organic matter, the use of impure acetic acid, or the use of a newly mixed iron developer, being amongst the most common causes.

**J. C. (Belfast).**—There is no substitute for enamelling card pictures which will produce any similar result. Varnishing has been attempted, but not successfully. The enamel paste to which you refer gives a very good result, and improves the picture, but the result is nothing like enamelling with gelatine and collodion. You may obtain the enamel or encaustic paste of Newman, of Soho Square. We cannot answer letters on photographic subjects by post.

**F. C. S.**—The chief defect in the prints you enclose is flatness, from the presence of too much diffused front light. The lighting is best in the portrait of a young lady in light dress, kneeling on a chair. A trace more intensity in the negatives, or a little better printing, would have made it a good picture.

**GEORGE.**—Our recommendation of pyroxyline made at a low temperature was for a specific purpose, the object being to make collodion for enamelling purposes. For negative collodion, we should not recommend such pyroxyline. It is very difficult to buy pyroxyline of uniform quality, and almost as difficult, without much experience, to make it of uniform quality. If you wish to make your own, you will enter upon a very interesting but very perplexing series of experiments, not without some risk. It would be quite impossible to give you full instructions in this column, as several pages would only give you an outline of the operations and the varying conditions and modes of dealing with them. You will find some useful details in all our YEAR-BOOKS except the last two or three, which you may usefully follow. You may obtain good cotton-wool for the purpose of most chemists. Coralline had only been employed experimentally, and each experimentalist has varied his proportions, trying various proportions to get various tints. Most London photographic chemists will be able to supply you.

**ROSE.**—Negatives which have become stained by standing unvarnished are somewhat difficult to deal with. You had better first run an edging of wax or black varnish round the edge to prevent the film leaving the glass when wet again. Then wet the film and supply a ten-grain solution of cyanide of potassium. This will probably remove the stains; but you must watch carefully, or it may also dissolve the image. When the stains are removed, wash well, dry, and varnish.

**S. L. D.**—The mottled, imperfect character of the prints you enclose is the result of using a weak, exhausted silver bath for exciting the paper, and probably very little of it in the dish. The strength of the printing bath should be kept up by adding silver or fresh strong solution from time to time; sufficient should be poured into the dish to fill it at least from half an inch to an inch deep, and it should be stirred or shaken up after exciting a few plates.

**R. B.**—You will find the promised details of the Lambert-type method in the present issue. It is, we understand, patented in this country, but the specification is not yet published.

**F. D. P.**—"White hard varnish" is a spirit varnish; diluted with an equal quantity of methylated spirit it is said to make a good negative varnish, presenting a tooth for pencil retouching.

**S. CUMBRIAN.**—The chief defect of the card enclosed is the presence of too much evenly diffused light, so that the face is flat, lacking any definitely marked light and shadow.

**G. M. R.**—The brown discolouration in your toning bath will account for its refusing to tone, as a decomposition has undoubtedly taken place. It has probably been touched with fingers contaminated with some other chemical. Probably you have touched the hyposulphite fixing solution, and then touched the toning bath. You can only throw the solution amongst residues.

**D. T. L.**—The presumption is in favour of prints enamelled with gelatine and collodion being more permanent than those not so treated; but this is not absolutely certain, inasmuch as the cause of fading is often in some imperfection in the fixing operations, in which case the print carries the seeds of destruction within itself, and no protective measures will save it.

**THE CRAWSHAY COMPETITION.**—We have received, just previous to going to press, and too late for insertion in this number, another letter from Mr. B. J. Edwards, reiterating his statements of last week, affirming that he is prepared to prove that the erroneous announcement issued in the latter end of September was approved by Mr. Crawshaw, and asking that the award may be cancelled. As we have said before, a reference to any of the announcements issued by Mr. Crawshaw will show that Mr. Edwards is in error. But in any case, it is not a question for our discussion in these columns, as a charge of error against the jury, or a request for a reconsideration of their decisions, must be made to themselves, through their secretary, Mr. Pritchard, as it can scarcely be supposed that, in any case, they could take such steps in response to a letter in a journal.

**J. BRIER, JUN.**—The Secretary of the Bengal Photographic Society is J. H. Bennertz. We presume, if addressed as "Secretary of the Photographic Society at Calcutta," a letter would find him.

**V. HATCH.**—We will give the matter attention in our next.

Several Correspondents in our next.

**METEOROLOGICAL REPORT FOR SEPTEMBER.**

BY WILLIAM HENRY WATSON.

Observations taken at Braystones, near Whitehaven, 36 feet above sea level.

Date.	THERMOMETER.			BAROMETER.			Direction of Wind at 9 a.m.	
	Morning.	Noon.	Night.	Morning.	Noon.	Night.		
1	61°	61°	60°	29.20	29.37	29.61	S.	Heavy thunder storm this morning, with lightning. Showery all day.
2	60	61	59	29.6	29.68	29.75	E.S.E.	Rain a.m.
3	58	60	56	29.72	—	29.60	S.S.E.	Showers a.m. and p.m. Lightning at night.
4	54.3	58	56	29.68	29.72	29.83	S.W.	Fair, but gloomy.
5	56	57	56	29.80	29.80	29.72	W.S.W.	Showers p.m. Gloomy all day
6	57	61	58	29.79	29.80	29.78	W.S.W.	Fair, gloomy, and sultry.
7	60	61	58	29.81	29.81	29.78	S.	Showers noon. Gloomy all day
8	58	—	58.5	29.78	—	29.54	—	Rain from 11 p.m.
9	54	60	54	29.29	29.25	29.20	S.S.W.	Heavy rain this evening. Lightning 10 p.m.
10	56	58	54	29.20	29.21	29.35	W.	Very stormy. Rain a.m. & p.m., with strong wind.
11	56	56	57	29.40	29.35	29.21	W.S.W.	Rain from 11 a.m. till 9.30 p.m.
12	54	62	53	29.59	—	29.79	—	Heavy rain this morning. Sunny during the day.
13	53	57	47	30.02	30.09	30.14	E.	Fair and sunny.
14	54	61	58	30.01	30.07	29.97	S.	Fair and generally sunny.
15	59.8	60	57	29.80	29.80	29.88	S.S.W.	Rain about 1 p.m. to 4 p.m. Gloomy all day.
16	52	—	50.5	29.81	—	29.84	N.	Fair and sunny
17	53	58	56	29.79	29.76	29.54	N.W.	Rain morning and night.
18	55	—	55	29.67	—	29.80	N.W.	Showers a.m. Gloomy all day
19	56	58	58	29.79	29.75	29.71	S.W.	Drizzle a.m. and p.m., with strong wind.
20	58	60	57	29.66	29.64	29.58	W.S.W.	Fair, but gloomy.
21	58.3	66	58	29.50	29.37	29.37	S.	Rain a.m. and p.m. Very heavy from 3.30 till 7 p.m., with thunder & lightning.
22	57	64	58	29.58	29.30	29.50	S.	Very heavy rain, with strong wind, p.m.
23	56	59	49	29.80	29.84	29.88	S.S.W.	Fair, but gloomy.
24	56	60	50	29.93	—	30.00	—	Fair and sunny.
25	56	58	56	29.99	29.98	30.00	S.	Rain a.m. and p.m.
26	56	60	57.5	30.06	30.04	29.04	S.W.	Fair. Cloudy.
27	56	66	57	29.84	29.80	29.78	S.S.W.	Fair, but cloudy. Sultry.
28	60	62	58	29.53	29.44	29.34	S.	Rain a.m. and p.m.
29	54	53	—	29.38	29.28	—	S.W.	Showers, with strong wind, a.m. and p.m.
30	53	54	53	29.54	29.59	29.56	S.W.	Rain, with strong wind, a.m. and p.m.

From the above data I arrive at the following:—

	Mornings.	Noons.	Nights.
Maximum temperature	... 60°	... 66°	... 60°
Minimum ditto	... ..	... 52	... 53
Mean ditto	... ..	... 56.4	... 59.6
Mean ditto of whole	... 57.2	... ..	... ..

N.B.—The temperature in direct sunlight on the 12th, 13th, 14th, 16th, and 24th was 113°, 110°, 100°, 110°, and 96° respectively; averaging 106°.

Number of days on which rain fell	... ..	... 20
Number of fair days	... ..	... 10
Number of fair days on which it was sunny	... ..	... 4
Number of fair days on which it was gloomy	... ..	... 6

**Brilliant Meteor.**—On the evening of the 13th September I noticed a very brilliant meteor—so much so that I could distinctly see at a distance of a mile—shoot across the sky at about 8.57 p.m., from S.W. to N.N.W., at an elevation of 50 degrees.

**Curious Views as to the Size of the Moon.**—Until about two months ago I was unaware of any considerable difference as to the apparent size of this "nocturnal luminary." Since then I have enquired of several persons, and have found those who describe it:—A, about the size of a shilling piece; B, about the size of a "cart wheel;" and C, from 12 to 18 inches in diameter. Is not this fact curious?

Braystones, near Whitehaven, October 3rd.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### MINIATURE PAINTING AND PHOTOGRAPHY—M. MERGET'S FURTHER EXPERIMENTS IN PHOTOGRAPHY—AN IMPORTANT APPLICATION OF PHOTOGRAPHY OVERLOOKED.

*Miniature Painting and Photography.*—That poor Miss La Creevy and her art are to be heard of no more is, of course, due to photography; and it is well sometimes to remember, when one hears the camera and its productions held up to scorn by cynical painters, that, at any rate, bad as photographic portraits sometimes are, they are infinitely superior to the daubed miniatures of fifty years ago. We may laugh at *carte-de-visite* pictures, showing models in all sorts of impossible attitudes and situations, but, miserable as many of them are, they are far more like nature than were the productions of the ordinary miniature painter of days gone by. A young gentleman in a very vermilion uniform, flourishing a sabre; portraits of naval dress coats, with faces looking out of them, and telescopes attached; a literary character, with a high forehead, pen and ink, six books, and a curtain; a touching representation of a young lady reading a manuscript in an unfathomable forest; a charming whole length of a large-headed little boy sitting on a stool with his legs foreshortened to the size of salt spoons; and old ladies and gentlemen smirking at each other out of blue and brown skies: these are descriptions given by Dickens of miniatures in his time, and how like they were to nature we need not speculate. Miniature painting went out like a candle on the advent of Daguerreotype; but while the new art was an enormous boon to the public, it naturally enough ruined many a miniature painter. Sir William Ross appears to have been the last great painter of miniatures, and he, fortunately for himself, died just before the arch-enemy of his class made its appearance. His successor, Mr. Thorburn, seemed in a fair way to reap a fortune and reputation equal to his master, but photography put a sudden end to any hopes he had entertained in the matter. In the work just published of the life of Samuel Lover, we learn that this favourite author and ballad singer attempted to earn a livelihood at miniature painting, and came to London, indeed, for that purpose; but, fortunately for him, his friends dissuaded him from the idea. He was once commissioned to paint a miniature of the Princess Victoria, but, being unable to leave Ireland at the time, he missed this first step in life, which otherwise might have constituted him the greatest miniature painter of the day: in which case, as was wittily observed at the time, the office of "Miniature Painter to the Queen" would have fallen to a Lover instead of a Hayter. The best miniatures of the present day are without doubt our photographic enamels.

*M. Merget's Further Experiments in Photography.*—M. Merget, of Lyons, whose process of printing by mercury vapour created some stir two years ago, has been continuing his experiments in photography, and has lately published a new method of copying engravings or sketches on paper by printing through them. He says that moisture exercises a great influence upon the decomposition of salts sensitive to light, and this fact he employs in his copying process. He covers an engraving with a thin layer of a sensitive salt, and, slightly moistening the surface of the paper, a metallic film is formed that allows the paper to be seen through. If the layer of sensitive salt is allowed to dry, the salt is reduced in another way, and the metallic film adheres to the paper and appears very dark. By making use of this action he is enabled to copy engravings so as to produce all the fine and strong lines. M. Merget further holds that all cases of photo-chemical action are much influenced by the presence of some substance which acts as starter of the decomposition. He finds, too, that many substances, of themselves insensitive, are capable of

increasing sensitiveness in other bodies; thus oxide of zinc, if mixed with nitrate of silver, renders the latter exceedingly sensitive. Iodide of silver, as we know, is less sensitive than bromide and chloride, but, if mixed with nitrate of silver, the mixture is readily acted upon by light. This circumstance, M. Merget tells us, depends upon the decomposition of the nitrate by the iodide, and the subsequent reduction of the silver salts thus formed.

*An Important Application of Photography Overlooked.*—"Roman Imperial Profiles" is a work published by Messrs. Longmans, containing "a series of more than one hundred and sixty profiles enlarged from coins," arranged by Mr. G. E. Lee. One would have thought that this was a book of all others in which photography might be employed with peculiar advantages, for reproductions by means of the camera of profiles from genuine coins would be as valuable, almost, as the originals. Indeed, Mr. Lee's earlier work, "Roman Imperial Photographs," consisted of transcripts of this kind, and were, therefore, well worth studying by antiquarians and observers of character. The difference, in such a case as this, between pictures produced by photography and those sketched by a draughtsman is obvious, for the latter would be quite worthless as a truthful record beside photographs, even of the most imperfect character. Moreover, the employment of the camera prevents all kinds of tampering in the process of copying, and we see the imperfections just as well as the beauties of the work: and this, to a student or connoisseur, is of the greatest importance. In taking a photograph of an historical record, what should we say, for instance, if some of the features had been retouched and altered? And yet, in the work to which we have referred, the author frankly admits that he has made a most vital change, such as would be almost impossible in photography. He says, in regard to these sketched copies of the profiles, that "the only part of the face in which possibly some license has been taken is the eye. Though the earlier coins are, of course, in a higher style of art than the later ones, yet even in the earlier coins the eye seems to have been often imperfectly represented; and in the later mints it has been drawn quite inaccurately. In the eye, therefore, Mr. Croft has corrected their bad drawing, and this can hardly be called a departure from the original." We doubt very much whether Mr. Croft would be able to make a better job of it than the ancients; but in any case it would have been far better to show the original as it was, with all its imperfections, than to attempt to alter, and thereby modernize, the work.

### FRENCH CORRESPONDENCE.

WHEN working the wet collodion process, it not infrequently happens that streaks and marble-like marks appear on the plate, upon the action of the sulphate of iron developer; these defects occur usually at the lower portion of the plate, where the silver solution has accumulated. They take all sorts of fantastic shapes, and appear brown by transmitted light, while viewed by reflected rays they have a silvery-grey aspect.

These marks can be easily removed with a soft brush under water, but the place they occupied has then no trace of the photographic image, and, consequently, the developer has produced an incomplete result. The marble marks are very prevalent when a silver bath is employed which has been used some time during hot weather. M. le Comte de Courten tells us a very simple way to prevent this kind of defect, which often renders clichés unserviceable which otherwise would be quite faultless.

On taking the plate out of the frame, after exposure, our ingenious correspondent leans it against the wall, collodion face outwards, resting it upon filter paper. He then takes a very clean sheet of the same paper (or, better still, of Berzelius paper), about five centimetres broad, and sufficiently long that he can apply it lightly to the lower

part of the collodionized plate to absorb the superfluous liquid. The paper is applied very gently and without any pressure or friction. The effect is most remarkable: the developer, which is used without stint, then exercises a most uniform action over the plate, and it flows equally over the whole of the latent image.

I spoke in one of my previous letters of the apparatus invented by M. Van Tenne for use with artificial light, not only for enlarging photographs by transmitted light, but also for amplifying opaque objects upon paper. Since then I have had an opportunity of personally experimenting with the Reflectoscope (for such is the name given to the apparatus), and I am now in a position to add a few interesting remarks to my previous communication.

I have said that the illuminating power may be furnished either by means of a magnesium light (Solomon's) or by an ordinary lamp, or, better still, by an oxyhydrogen apparatus. In the first case—that is to say, when a magnesium lamp is used—it behoves one to get rid of the inconvenience arising from the disengagement of fumes which become deposited on the condenser and upon the bright surface of the reflector in the form of a fine powder. This phenomenon, it may be guessed, militates very much against the reflection and transmission of the luminous rays. M. Van Tenne has succeeded in completely getting rid of the vapour by means of a current of air, which takes off the dense white smoke as soon as it is disengaged. In this way the pose may be reduced by some seconds, a most important consideration in face of the high cost of magnesium.

The oil lamp, with double current, produces a light almost white in character, and of a very powerful nature, which allows one to secure an enlargement within the space of a minute and a half. As to the oxygen gas, it may be easily introduced by means of an india-rubber tube, one end of which is attached to a reservoir and the other to a lamp furnished with a stopcock. I have said that the reflector is a spherical one. In this I was mistaken. Its form is an irregular ellipse, the curves of which are calculated in such a way that all the rays emitted by the source of light, and dispersed in every direction, are collected and directed in one path by the condenser, so that none of the rays are lost. It is in this way that the power of the apparatus is secured.

M. Van Tenne has even found a means of rendering more photogenic the light from an ordinary lamp fed by oil. He places before the condenser a blue glass, which stops all the yellow rays, and only allows those of an actinic nature to pass.

While discussing this subject, I must not forget the very curious experiments which M. Geynet has undertaken, and which ought to bring with them a mass of new revelations. Although I can scarcely enter at present into the details of experiments which have as yet scarcely begun, I may state that they confirm the theory expounded by M. Ducos du Hauron in the description of his heliographic method. By taking the three monochrome clichés which M. Ducos employs, and impressing by their means some sensitive collodion plates which are developed in the ordinary way, he obtains with the negative produced by means of the red glass a blue image; with the negative furnished by the green glass, a red print; and with the negative from the violet glass, a yellow print. In this manner, without changing in any way the method of operating, we obtain direct monochrome prints of different colours by the simple decomposition of light, and without having recourse to pigmented tissue.

M. Geynet, who is conducting his experiments with energy, proposes to give a demonstration at the first meeting of the French Photographic Society, on the 6th November next, and it is not unlikely that, by that time, he will have obtained several important results connected with this important subject.

In the face of the progress which has been made

recently in the matter of printing with fatty inks, and with the view of employing in the process the ordinary materials used by printers, one of our ablest mechanics, M. Poirier, has taken it into his head to construct a press which responds to all the wants generated by recent progress, and, I may add, he has completely succeeded in the matter. I have seen this press at work, and it seems to answer all purposes, for it may be used equally well for printing from blocks obtained by means of photography upon glass, upon lithographic stone, or upon metal; in other words, it serves for printing from Albert-type plates, as also from photo-lithographic and phototype plates, and for helio engraving. Its dimensions are such as to render it a most useful instrument. It can be worked with great facility, and its price is relatively very low. These are qualities which will ensure the invention every success.

The readers of the PHOTOGRAPHIC NEWS have, no doubt, not forgotten the name of M. Charles Nègre, nor the valuable heliographic work which that gentleman so successfully carried out. This artist was at once both a distinguished painter and a photographer of the first rank, and was one of the first to secure printing blocks upon steel by the sole action of light, and the beauty of these results, which he submitted to the public, contributed much to encourage him in continuing experiments in this direction. M. Nègre adopted first of all the process invented by Nicéphore Niépce, and modified by Niépce de Saint Victor; but he shortly afterwards perfected the process in the following manner:—

The steel plate was covered first of all with a varnish of bitumen of Judea, or with a film of gelatine and bichromate of potash, and then printed in the sun, not under a transparent positive, as was the case formerly, but under a reversed negative obtained direct in the camera. In this way the sensitive film was acted upon in those parts corresponding to the shadows of the image, and the steel plate, after removal of the soluble varnish, was uncovered in those parts corresponding to the high lights. The plate was then plunged in a gold bath and subjected to electric action. The plate became covered with an uniform coating of gold in all parts corresponding to the lights of the image, where the plate has been laid bare; whilst the portions corresponding to the shadows, and still covered by the varnish, were only covered with the gold in proportion as the light had acted upon them. The metal plate afterwards, when freed from all traces of varnish, had upon its surface a very adherent gold image, forming a perfect damascened image. The gold being proof against any attack by acid, it suffices to treat the surface with a dilute acid to etch the steel wherever it is not protected by the deposit of gold. In this way an engraved plate was formed presenting all the gradation of tints, from the purest whites to the most vigorous blacks.

For some time past we have heard nothing of M. Nègre, nor of his work; but one of our principal publishers has just issued a magnificent work by the late Due de Luynes, entitled, "A Voyage in Syria," illustrated by heliographic blocks executed by M. Nègre. The helio-engravings are produced from clichés collected by the noble traveller himself, and the result of the whole work is very successful. We are thus afforded proof of the circumstance that M. Nègre has not abandoned the good work on which he has been so long engaged, and we may now hope that he will prosecute his experiments with renewed activity.

ERNEST LACAN.

#### THE PRESS AND THE EXHIBITION.

[It will be seen in our next extract that *The Standard* is less accurate than usual in more points than one, attributing in one case Woodburytype prints to the Autotype Company, and, whilst ignoring altogether the Crawshaw competition and

prizes, noticing some of the competing pictures as an integral part of the Photographic Exhibition.—Ed.]

(From THE STANDARD.)

The Photographic Society of Great Britain have now on view at the Gallery of British Artists, Suffolk Street, Pall Mall, many examples of the skill of the more distinguished members of the profession. We may thus note the changes and improvements of the year made in the practice of an art which has become of interest more or less to every home.

Among the portraits, those by Julia M. Cameron would seem to take the highest place, because they best realize the style of the best painters, past and present. Take, for examples, the portraits now exhibited by this lady of "Little May Maurier," "Egeria," and "Little Rachel Guernev," taken direct from life. The light and shade call to mind the best pictures of the old schools. The portrait of "May Maurier" delights by its subtle low tones, which soothe the eye as much as some specimens in the same room distract by their abruptness and want of harmony. Julia M. Cameron's head of "Little Rachel Guernev" wears a peculiar lustre—the eyes are mirrors of light; while "Egeria" will claim attention for the nice care shown in the modelling of the face and neck. Whoever contemplates these portraits with care will view ordinary photographs only for the interest which they may have as likenesses of friends or of people of distinction.

Among the examples of landscape, we were attracted by the pleasant rendering, by Mr. J. Brier, of "Pont-y-Pair, Bettws-y-Coed." Here the boulders which enclose the quiet pool, and the dainty foliage which surrounds it, are exquisitely suggested. Photographers are never more happy than when rendering the charming effects of a shady avenue, like Mr. W. Nicholson's view of "Bonchurch Valley and Pond," in which the nicest gradations of shade are brought out with delicate truth. Photographers revel in ferns and flowers. Mr. J. Brier has met with a marvel of this kind at "Undermount, Bonchurch."

Architecture is rendered to perfection. Mr. Henry Piper has some views in which buildings are the chief features. His "Warkworth Castle," with river and woody slope, is fresh and bright as day; his "Guisboro' Abbey, Yorkshire," is expressed with a sharpness that would almost seem unreal; every stone that goes to make up the venerable pile looks as crisp as the chisel left it. The collection is rich in photographs of famous ruins. Mr. Peudryl Hall has a number from which it would be difficult to select one in preference to the others. The "Courtyard, Acton Burnell Castle," and "Conway Castle, from the Bettws-y-Coed," are, like "Building, Abbey, Nave, and Chapter-House," rendered with feeling.

Colonel H. Dixon exhibits a series of effective views in India, chiefly of famous temples and palaces.

Very much in contrast with the clear atmosphere of Colonel Dixon's Oriental scenes is Mr. Reuben Mitchell's little photograph called "Threatening Storm—On the Road," which is soft and humid to look upon as an April shower when white-edged clouds pass swiftly on their way.

Messrs. A. and J. Bool can deal with an entanglement of weeds, plants, and wild flowers, as witness their landscape entitled "A Shady Nook." For a first-rate true portrait of an old tree commend us to an example in the collection, an enlargement by Edwards's process from a negative by Mr. Henry Cooper. In this instance the lens has done its work in revealing the effects of storm and tempest, wrinkled age, and the havoc made by foolish visitors who from time to time have made incursions in the bark to inscribe their names.

There is a charming bit "On the Cherwell—Early Morning." Tall, graceful elms, which half conceal a Gothic tower, and a narrow stream well fringed with sedge. It is by Mr. J. Vaughan. Mr. J. Sutcliffe has specimens of soft, dreamy landscapes. One a calm lake scene with graceful trees, light as the birch, drooping over the water. Six views near Melton Mowbray, by Mr. C. A. Fernely, have the true, ripe, rustic tone so inviting to the wanderer. In the same feeling and kindred subject is Mr. F. Beasley's valley at Medeham, where the church lies half-buried by the near clump of trees.

Scattered about are many examples of the autotype process, by Messrs. Spencer, Sawyer, Bird, and Co. We were struck by the wonderful resemblance of nine of these autotype pictures shown in one frame. They are taken from Turner's Liber Studiorum. The selection would appear to have been made to show how the varied effects intended by the great original master may be perpetuated by the autotype process. We have morning, sunny and soft, stirring life on the ocean, village calm, and gloom

intense, where black clouds hang over a treeless moor. We need not enumerate the variety of good things which are exhibited by Messrs. Spencer, Sawyer, Bird, and Co. Under the heading "photography in the printing press" are landscapes and portraits alike successfully treated by their process.

Those who delight in portraits will find a variety of all sizes and proportions. The collection includes photographs of almost every known subject, far too numerous to name. An alphabetical list of exhibitors is appended to the catalogue, which will be of service. The society have done well to provide space for the influx of contributions which have poured in from all quarters, in addition to the contributions of former exhibitors.

(From the OBSERVER.)

The number and quality of the contributions sent in have justified this society in departing from their former rule, and holding their nineteenth annual exhibition a month earlier than usual, when the large galleries of the Society of British Artists in Suffolk Street are at their disposal. One of the main features of the present exhibition is the display of photographs in competition for the series of prizes given by Mr. Robert Crawshaw. These prizes are divided into two classes, one for portraiture on a large scale, the other for landscapes, and a separate room has been set apart for each. In both of them, the works which have gained prizes show the high state of perfection now attained in the art of photography. At the same time, we cannot but feel that the nearer is the approach made to imitative perfection, the more obvious and marked is the distinction between this art and that of painting in its nobler and more intellectual form. There is apt to be something almost painful in a large life-sized reproduction of human features; and we seem to lose the expression of a face, as we do that of a natural scene, while we are engaged in tracing the fidelity of transfer of every detail. The further we descend into particulars the more do we feel the want of that artistic spirit of order which marshals the facts of a subject, and so presents them to the mind of the spectator as to convey to him the same impression that the facts themselves have conveyed to the mind of the artist. But it would be a mistake to suppose that the photographer has not considerable scope for the exercise of artistic taste in the selection and arrangement of the objects he imitates, as well as in the manner of applying the resources of optics and chemistry at his disposal. The present exhibition is not without examples of this higher view of photographic art, but they are the exception, not the rule. In portraiture on a large scale, Mrs. Cameron employs the device of placing the sitter a little out of focus, so as to give an agreeable softness to the shadows, and convey the likeness in the light and shadow rather than in the surface of the skin. Without pushing this expedient so far, the winners of the Crawshaw prizes—namely, Messrs. Chaffin and Sons, Robinson and Cherrill, R. Crawshaw, and R. Slingsby—have nearly equally avoided hardness of effect. While their portraits are taken direct from life, Mr. C. Ferranti gains a fourth prize by the most successful enlargement of a head from a small photograph. Still, however, we prefer the smaller portraits, such, to select one example out of many, as Mr. R. Faulkner's delightful frame of children (69). The exquisite effects of landscape, by Messrs. Robinson and Cherrill, who take the first prize in that department, and are thus in the first rank in both classes, go further to outweigh what we have said about the limits of the art. Nothing can surpass the tender beauties of the luminous sky in "Repose" (276), while in all their works the composition is thoroughly artistic. There is less art in the large Welsh views of W. D. Sanderson, which are justly entitled to the second prize as photographs. The three French seaports (291 to 293), by Sydney Smyth; a Small Haycart (67), by F. M. Sutcliffe; "Summer Shade" (77), by H. Whitfield; and a frame of landscape studies (463), by H. B. Berkeley, are noticeable for picturesque quality. Of the last-named, and the portraits (121 to 127) by S. and E. White, the neat and effective framing is also worth notice. Specimens of enlargement of landscape, as well as portraits, and series of views in New Zealand, by D. L. Mundy; India, by Colonel H. Dixon; and the Asturias, by Messrs. M'Andrew and Stennings, are among the other attractions. The mechanical printing processes and enamels are also fairly represented. The conductors of the exhibition justly regret that there are but few instantaneous views and dry-plate subjects. These, indeed, are among the most valuable applications of photography. But we can scarcely share in their desire for more "composition pictures." They are apt to be but a weak kind of masquerading, such as Mrs. Cameron's "King Henry" (205), or a pumping of

sentiment, such as we see in the group (202) of sham fisher children playing at saying prayers for their father at sea.

(From the SOUTH LONDON PRESS)

Every one interested in photography—and who does not take an interest in this beautiful art?—should make a point of seeing the Photographic Society's Exhibition at the Gallery of British Artists, Suffolk Street. It is open for a very short season—only some three weeks—and this is to be regretted, since, as an exhibition, it is unique. Here may be seen the very best specimens of the art, each interesting in itself, while in combination they serve to show the progress made, and the perfection photography has attained to. A great part of the gallery is occupied with works sent in for the Crawshaw Competition—that is to say, for prizes, over £200 in amount, given by Mr. Robert Crawshaw, of Cyfartha Castle, Merthyr Tydvil, as an encouragement to experiments in special branches of the art. The first prize (£50) is taken by Messrs. Chaffin and Son, of Yeovil, for large heads, from life, and rather a curious incident may be noted respecting this. When the judges awarded this prize they telegraphed their decision to Yeovil. In the meanwhile young Mr. Chaffin had come to town, and, wholly unconscious of his good fortune, went to the conversation with which the gallery was opened on Tuesday night. His delight may be imagined when, on approaching the specimens he had sent in, there, hanging on the wall, he saw the principal one surmounted with the information—"Chaffin. First prize £50." The congratulations of his brother artists convinced him that the judges were not "chaffin'," in spite of their announcement; and Mr. Crawshaw, who arrived in town next day, added to his gratification by stating that he thoroughly endorsed the opinion of the judges as to the pictures deserving the prize. Bishop Colenso was, by the way, a visitor on the opening day, escorting Mrs. Crawshaw round the gallery.

## PHOTOGRAPHY FAMILIARLY EXPLAINED.

BY ALFRED H. ALLEN, F.C.S.\*

THE action of light on chemical compounds has been shown by careful investigations to be far more general than was formerly supposed, though comparatively few substances are acted on with sufficient rapidity to prove useful to us in photography. I am not aware that there is a single case in which the action of light causes combination; light is eminently a separative force, invariably (at least as far as we know at present) effecting decomposition.

It is true that a mixture of equal volumes of chlorine and hydrogen gases is powerfully affected by light, with production of the compound body hydrochloric acid; but we have very strong reasons for believing that the combination is only a secondary reaction, the first action of the light being to decompose the molecules of chloride of chlorine, and perhaps the hydride of hydrogen, the nascent elements then entering into combination with formation of chloride of hydrogen. That the molecules of chlorine do suffer decomposition by light is highly probable, from the fact that ordinary chlorine gas suffers a permanent change in bulk by exposure to light. The rapid combination of chlorine with hydrogen has been successfully used by Bunsen and Roscoe for determining the actinic power of daylight and various flames.

The actinic chemical change, and, therefore, of being used in photography—is not always in proportion to its luminosity, and, therefore, the brightest day is not always the best for taking photographs. Of the gorgeous prismatic colours I now throw on the screen, the blue and violet have the greatest actinic power, and the dark ultra-violet space greater still; so that in the same way that we may have aerial vibrations occurring so rapidly as to produce no sound, so we have ethereal vibrations of such rapidity that they do not affect our eyes, though the sensitive collodion film can see them.

Among bodies sensitive to the action of light the com-

pounds of silver stand pre-eminent, and nearly all our ordinary photographs are taken through their agency. When I add a solution of common salt to this nitrate of silver, you observe the formation of a white curdy precipitate known as chloride of silver. When exposed to light this body gradually darkens with liberation of chlorine. If we soak paper in common salt solution, and, when dry, float it on a solution of nitrate of silver, a deposition of the chloride of silver takes the place in paper itself, and in presence of an excess of nitrate of silver and of the organic matter of which the paper is composed, the tendency to darken in the light is much increased. If albumen is also present the paper is still more sensitive, and in this form constitutes the ordinary sensitised paper on which our cartes are printed. If a fern-leaf or piece of lace be laid on such prepared paper, and the whole exposed to light, the unprotected portions of the paper are darkened, and a "negative" print is obtained, which may be rendered permanent by soaking the paper in some liquid which will dissolve the unacted-on chloride of silver without affecting the darkened portions. If we print from a negative picture (already obtained by another process), we get a "positive" impression on the paper, and it is by this method that our ordinary "cartes" are obtained. I am unable to use paper for my experiments this evening, as prolonged exposure to a good light is essential to success; but I will employ a far more delicate preparation—in fact, the same which is ordinarily used in the camera for taking negatives.

By adding nitrate of silver to this solution of iodide of potassium you see I obtain a cream-coloured precipitate of iodide of silver, and though light has but little action on this body when alone, in presence of excess of the nitrate it is exceedingly sensitive.

Instead of using paper I employ "collodion," made by dissolving a species of guu-cotton in a mixture of alcohol and ether, and when poured on this glass plate the liquid rapidly dries up, leaving a thin tough film impregnated with certain iodides which the collodion has held in solution. I next immerse it in this bath of nitrate of silver, when the cream-coloured iodide is produced in the collodion film, which also absorbs an excess of the nitrate.

I now extinguish all but the yellow light with which the table is illuminated, and remove the plate from the bath, when you observe that it is covered with the yellowish silver iodide. On the face of the collodion film I now place this negative portrait, and will act on the silver compounds by exposing it to the light of a short length of burning magnesium wire.

But first I will cover half the negative with red, and half with deep violet glass. After the burning of the magnesium, the print is taken, but you observe that the plate appears in no way changed; it requires to be acted on by some deoxidising agent, which causes a reduction of metallic silver in the portion exposed to action of light without affecting the parts which were protected by the opaque portions of the negative. On pouring an acid solution of ferrous sulphate on the plate, the picture gradually becomes developed, and after washing and "fixing" by dissolving the unacted-on silver compounds in cyanide of potassium, I place the plate in the lantern, and you see the image of it plainly projected on the screen. But the remarkable thing is, that the half which was covered with red glass has no picture on it, while the portion exposed under the violet glass is perfect in every detail. This curious fact deserves further study, so I produce the lime-light spectrum again, and place a second sensitised plate in the beam. On developing this you see that the action has occurred in the blue, violet, and ultra-violet region, the photograph gradually shading off towards the red end, where no change has occurred. This gives us the reason why photographers work by yellow light, for you see this yellow glass stops all the rays which we have found useful in taking a photograph. But we must not suppose that no actinic power is associated with the red end of the spectrum. On the contrary, chlorophyll is rapidly de-

\* *English Mechanic*. Abstract of a lecture delivered before the Hull Literary and Philosophical Society.

composed by red light, and bromide of silver is sensitive to all the rays of the spectrum. Naturally, a compound is most affected by the light of that colour (or refrangibility) which it most readily absorbs. Thus, chlorino absorbs the blue end of the spectrum (thus acquiring a greenish yellow colour), and consequently is most affected by the blue and violet rays. Iodide of silver has a yellowish colour for a similar reason. But chloropoyll largely absorbs the red rays, and consequently is affected by red light.

An extension of this principle in a novel and unexpected manner has lately rendered it possible to obtain photographs in the natural colours of the objects, and though the pictures are not remarkable for brilliancy or permanency, it is a step in the right direction, and foretells a more perfect success.

I should like to show the curious process of "development" in actual progress, so I will take a print on collodion by exposing a sensitive plate under this negative picture of your President to the action of this gas flame, and then immersing it in this diluted developer contained in a glass cell, I use it as a lantern slide, taking care to protect it from the action of the lime-light by the interposition of this yellow glass. There you see the picture gradually appearing on the screen, thus clearly showing the action of the developer on the exposed plate.

In the previous experiments I have merely printed on a sensitive collodion film through a negative picture, but of course the negative had first to be produced. On adjusting this lens at an appropriate distance from the screen, you see I obtain an inverted image of the gas flame. On exposing this collodion film at the focus of the lens I shall act on the silver compounds present, and after developing, &c., you see I have obtained a negative photograph of the flame. Any well illuminated object may be used, instead of an actual flame, but the exposure must be much longer.

Placing a sensitised plate in the dark slide of this camera, and illuminating this coloured print with magnesium light, I obtain a veritable negative photograph, which on placing in the lantern you see is an exact fac-simile of the original, except that the blacks and whites are reversed, and the blue and red tints have behaved almost like white and black respectively.

There is an extensive application now made of the fact that the bichromates are acted on by light with partial reduction to an oxide of chromium capable of forming an insoluble compound with gelatine. A glass plate is flooded with a solution of bichromate and gelatine, and exposed under a negative in the same way as sensitive paper.

On soaking the exposed plate in water, the unacted-on portion dissolves, thus leaving the exposed portions in relief, and after treatment with alum to cause hardening, the plates may be used for printing and various other purposes. Carbon (lampblack) or other inert pigments may be mixed with gelatine and bichromate, and then the film itself becomes a most perfect picture, and may be transferred from the glass to paper or other surfaces. In fact, the various applications of the gelatine process are capable of numerous modifications, according to special requirements, and of course the productions are quite independent of the action of light except in the first instance, so that while they have all the accuracy and detail of photographs, they have the advantage of allowing of almost unlimited reproduction, like other pictures produced by printing.

## Recent Patents.

### BURNISHING PHOTOGRAPHS.

BY HONORE MUHE.

THE following provisional specification of a patent for a burnishing process was abandoned:—

"This invention relates to an improved mode of and apparatus for polishing and glazing photographic proofs by submitting them to the action of a peculiar roller press and burnisher, which latter is heated by a lamp or otherwise during the

polishing process. This press consists of a roller the surface of which is just sufficiently roughened to insure the drawing in of the mounted photographic proof when presented thereto. Beneath this roller there is fitted an adjustable table, mounted on hinges at one end, whilst the other end is supported on powerful helical springs mounted on adjusting screws. This table is recessed immediately beneath the pressing roller, to receive any good burnisher—such, for example, as a strip of highly polished and hardened steel, glass, porcelain, or other like substance, capable of withstanding heat. On each end of the cylinder there is provided a slightly projecting shoulder or collar which rotates in contact with the surface of the burnisher at each end, and thereby prevents the photograph from being unduly pressed upon by the roller. On the axis of this roller there is mounted a winch handle for actuating the same. A lamp or other convenient means for heating the burnisher is situated immediately beneath the table. The surface of the table at the front part is ribbed with a view to facilitating the removal of the photograph therefrom on its leaving the burnisher. By subjecting the photograph (which is introduced face downwards) to combined pressure, and rubbing upon the surface of the heated burnisher, a brilliant glaze or polish will be imparted thereto."

### OBTAINING PHOTOGRAPHIC IMPRESSIONS ON COPPER PLATES FOR ENGRAVING.

BY HENRY BRADLEY.

THE following specification describes a mode of photographing on copper, so as to secure a satisfactory design to be followed by the graver:—

"In giving effect to my invention I will describe it as a quick and ready means for transmitting to a copper plate the view, object, or articles desired to be engraved on the same, and I effect this by a positive or negative application of photography. If the positive, I coat the plate by the agency of electricity with the thinnest possible deposit of silver, which deposit I afterwards oxidize by submerging the plate in a suitable acid, and on the front of the plate so silvered and oxidized I apply a coating of prepared wax, an essential feature of my invention, next a film of collodion, and when so prepared it is made sensitive with a solution of silver. The plate may then be placed in the camera for receiving and retaining through the medium of its lens the view, object, or other matter so produced, by which means a faithful representation of the matter to be engraved is transmitted to the plate. The plate is then taken from the camera, and undergoes a preparation of albumen and a coat of preservative, after which process it is ready for the operation of the engraver, who may proceed with his work with the thorough certainty that impressions printed from the finished plate will be faithful in outline and detail, thus saving the time of the skilled artist in working out the design and perspective effect for the engraver's guidance. Designs thus produced would be reversed by the process of printing, to avoid which, when desirable, I take a glass reversed negative, and then prepare my copper plate or other surface as follows:—I coat the copper plate in this case with a sensitive film prepared with wax, as in the positive process, and collodio-chloride of silver. The glass negative is then brought in contact with the so prepared surface with the aid of light, by which means a well developed and truthful positive is produced. It is then toned and fixed, and ready for the engraver to work on.

"I have described my invention for applying designs to be engraved on copper or metal plates; nevertheless, the same or modified process may be applied to surfaces for engraving of a non-metallic character.

"Though somewhat technical in my description, I have not thought it necessary to particularize the chemical compounds hereinbefore named in connection with the effectual realization of my invention, as skilled practitioners in the art of photography will well understand both the compounds and use of the preparations or chemicals named, and which invention simply consists in the application of photography in the manner herein described and set forth to the transmission and fixing on prepared surfaces, as herein named, pictorial, statuary, articles of vertu, manufacturers' designs, out-door views, or other matter, which may be enlarged or reduced, as desired, for subsequent engraving or etching, without the aid of artistic skill in drawing, or imparting to such surfaces the object or design to be engraved; and which I claim as of my invention, and desire to protect by these my in part recited letters patent."

## SECURING COPYRIGHT IN PHOTOGRAPHS.

NOTWITHSTANDING that a copyright law exists which should effectually protect the photographer against the unauthorized use of his work, we constantly receive communications from correspondents complaining of an especially irritating form of piracy to which they are subject, the more annoying because they rarely feel the matter of sufficient pecuniary importance to justify them in spending time and money in attempting to secure the legal remedy, which, although ostensibly available, sometimes eludes the grasp from some lack of experience in the mode of attempting to apply it. The kind of annoyance to which we refer at this moment does not consist in the production of photographic copies by a photographic pirate, and thereby injuring or destroying the sale of the original photograph. This is a commercial wrong, for which the photographer generally feels bound to seek a legal remedy, and, being a tangible wrong, it is rarely difficult to secure the remedy. But we refer to the practice of publishers of illustrated periodicals seizing the subjects which have cost the photographer much time and money to obtain, and engraving them not merely without permission or payment, but without the slightest acknowledgment or recognition of the source from whence the design is obtained, but often making some slight alteration to disguise them, serving them as Sheridan, in the "Critic," says "gipsies do stolen children, disfigure them, to make 'em pass for their own." The offence is in such cases as annoying as the remedy is doubtful, unless much experience and judgment are employed in putting the law in operation. In a recent note from Mr. England he pointed out two very barefaced copies of his Swiss views, copied without a word of acknowledgment, either of photography or the photographer, in a leading illustrated journal. This was by no means a solitary instance: parallel cases are frequently brought under our attention. As Mr. England remarks in his letter:—"The illustrated journals, whilst making use of photographs on every possible occasion, persistently try to ignore their indebtedness to the art."

We have more than once already called the attention of our readers to the formation of an association or company which aims to put an end to this especial evil, whilst conferring various other benefits. We learn from the *Illustration Company* that they have now completed arrangements for the establishment of a Central Registry of Copyright Photographs, where a complete record of copyright photographs will be kept, the company undertaking also to act as special agents in securing the due registration of such photographs at Stationers' Hall, and thus aiding photographers to secure protection. Our readers will remember that when the Fine Art Copyright

Act was passed a dozen years ago, our publisher undertook to enter photographs at Stationers' Hall for those photographers who could not undertake the duty personally, and has since continued to act for many of our readers. There cannot be a doubt, however, that photographers will find it advantageous to place themselves in relations with an agency devoted especially to such work, as well as to the negotiation between all parties interested in the sale or purchase of interest in the copyrights involved. It appears certain that an office undertaking to register, to record, and to negotiate such copyrights, and to secure, or advise in securing, a remedy in cases of infringement of copyright, meets an existing want, and must prove a boon to photographers.

## THE PHOTOGRAPHIC EXHIBITION.

### PORTRAITS AND STUDIES.

IN the present exhibition there are fewer subject pictures than we have seen in any similar exhibition for many years. There are no pictorial compositions, either in landscape or figure subjects, of important size or pretension, and comparatively few single figure studies which pass out of the domain of portraiture. Every year, however, portraiture, pure and simple, seems to take a higher pictorial character, and there is no lack in the present exhibition of fine examples of portraiture possessing high pictorial value: an important result, which may, no doubt, be largely attributed to the educating influence of the purely pictorial studies which the highest class of photographers have for years steadily produced.

Probably the most important pictorial "combination" at the present exhibition is No. 49, "The Spring," by Mr. A. Ford Smith, a clever composition, representing a couple of girls, with pitchers, at a spring in a bit of lovely country. The landscape portion of the work is very admirable: a bold foreground, good middle distance, and fine atmosphere effect on the mountains in the extreme distance. There is perhaps room for objection against the somewhat pronounced action of the figures, suggesting lack of ease and repose; but the picture is decidedly meritorious. The figure study by Herr Hugo Theile, of Dresden (52), has many charming qualities. A pretty little boy, quaintly dressed, rendered with singularly perfect photography, rich, delicate, brilliant, well-modelled, wins general admiration; but, as we have before said, it admirably illustrates a common photographic failing—the incapacity or indisposition to cut away any portion of a picture, not absolutely out of focus or stained, or in some way technically faulty. It is important in photography, as in literature, to learn "the last, the greatest art, the art to blot," or rather, let us say here, the art to curtail or limit. In this picture the part would undoubtedly have been greater than the whole: the cutting away of a few inches of unnecessary background would have made the portrait a picture. Mr. Rejlander is one of the few photographers who never err in this way. We sometimes desire that he would give us more, but we never have occasion to wish he had given us less. His frame of scraps (No. 6), containing studies of expression, contains almost material for a gallery in itself, if all the ideas were worked out. Three examples of portraiture (405-7) were also exceedingly fine. Mrs. Cameron contributes freely to the present exhibition, and many of her pictures have unquestionably charming qualities, despite technical shortcomings. No. 182, a portrait of Miss Isabella Bateman, illustrating the line, "Urania speaks with darkened brow," is a fine piece of pictorial work, admirably arranged; light, statuesque, drapery effectively rendered against the dark, leafy background. A study of the Magdalen (199) is very fine, as are also "Pray, God, bring father safely home" (a little child praying at its mother's knee), and "Kiss me, mamma" (204). King Harry the Eighth is a good portrait of a

well-known artist, but not so happy as a picture. An attempt to illustrate some well-known lines from Tennyson's magnificent "Maud," without being successful, is scarcely failure. The lines are:—

"There has fallen a splendid tear  
From the passion-flower at the gate.  
She is coming, my love, my dear;  
She is coming, my life, my fate."

There is a pleasant suggestiveness about the figure and treatment which will charm many. No. 203, "Queen Henrietta Maria announcing to her children the coming fate of her father," is the least satisfactory of Mrs. Cameron's contributions: a poor tricky scene, from an unwholesome modern drama, poorly rendered. There are also several other of Mrs. Cameron's studies, some possessing very good qualities. Jabez and Alfred Hughes send some good portrait studies. No. 167, a collodion transfer enlargement, is a very charming picture of young maternity, and an equally charming portrait. The pictorial qualities are fine, and the tone and photographic qualities generally are richer and more vigorous than is usually attained in collodion transfers. No. 132, a copy of a study of a lion's head by the late Sir Edwin Landseer, is a singularly brilliant and forcible example of what may be effected in collodion transfer enlargements. There are several other frames of very fine portraiture, and a capital frame of odd dogs, illustrating the same method of printing. A number of yachts off Ryde by the same firm are very interesting. Mr. G. Bruce sends a very perfect study of a cottage interior, with a fine old woman sitting, bible in hand, contemplating the approach of the inevitable messenger. The old lady is "biding His time," and will evidently hail its arrival. The work is singularly fine in all respects. "Thinking of Home" is scarcely inferior in many qualities. Mr. Faulkner's frame of children probably contains more to repay lengthened study than any frame in the room. It is marvellously full of interest. All the charming children in London seem to sit to this gentleman, and to assume their most winsome aspects, and few probably could infuse so much art quality into pictures often taken under great disadvantages. A pretty expressive portrait of a little child, by Mr. W. Fox, entitled "Astonishment" (89\*), is very interesting, as is also (153) "Papa's little pet," by W. Gillard, a print rendered not the less effective from the "mezzotint" treatment it has received. Mr. Werge's figure studies are novel in conception, and highly skilful in treatment. Dealing with dangerous materials, nude models, he has escaped the possible danger which attends such an experiment. In "The Senses," five photographs of a little naked boy, skilfully posed and admirably photographed, cleverly illustrate by varied action the five senses. His other subjects each contain a thought well expressed. The Misses Davidson are very successful in a charming little lady, entitled "Our Alice," but less so in "Jane Shore." We have before referred to the excellence of the portrait studies of Mr. J. M. Young. In addition to the portraits, he sends a subject picture, entitled "For dear Life," representing a ship-wrecked sailor clinging to a rock to escape being washed away by the surging tide. The photography is excellent, and the pictorial composition good; but the attempt is just outside the capacity of photography, which does not readily lend itself to the expression of the powerful action and emotion involved in such a subject, and hence the manufacture of the picture is too apparent. "The Old Story," by Mr. A. Johnson, of Wick, is a very good picture of two lovers, the old story being told with the effective aids of moonlight and fine scenery.

With the exception of the pictures sent for the Crawshaw competition, and the grand examples of auto-type enlargement, there is not much large portraiture in the exhibition. Col. Stuart Wortley sends one very fine female head, equally fine as a picture and perfect as a

photograph. Mr. Slingsby also sends one life-size head which is singularly rich and effective, delicate without weakness, vigorous without coarseness, and marvellously full of modelling and solidity. Mr. Crawshaw also sends a very fine large head; but his two female heads, a little smaller, "Meditation" and "Lucy" are still finer. We have before referred to Mr. Blanchard's portraiture as leaving nothing to be desired. Besides his portraiture pure and simple, he has some examples of more essentially pictorial work, which are wonderfully effective. No. 226, a beautiful Italian face, treated in the manner of a well-known picture, and 241, a costume portrait, are well worth careful examination. The portraits of Mr. Abel Lewis stand also in the highest class, both in photographic and pictorial excellence, a singular refinement characterizing every example. We have also before referred to the excellence of the portraiture exhibited by three Brighton artists: M. Boucher, L. Bertin, and Lombardi and Co. The last mentioned, although very fine, occasionally trench on a somewhat hard mechanical effect from excess of retouching on the negative. Some very good examples of portraiture are exhibited by Messrs. Vandyke and Brown. Mr. W. Street, of Waterford, has some good work, as have Mr. A. W. Wilson, Messrs. Barry and Co., Mr. Barnes, Mr. Hooper, and others.

Perhaps there is no finer or more interesting picture, in many respects, in the whole display, than the "Dead Stag," sent by Captain Horatio Ross. The noble animal lies where he has fallen, apparently, when shot, in the midst of a grand highland landscape, his noble head and the foreshortened body admirably rendered. A "Group of Ptarmigan," by the same hand, is good, but less effective. A "Donkey and Foal," by Mr. T. Edge, is very admirable, true to nature, and a fine picture. Mr. A. Nicholls sends some capital portraits of "Toads." Mr. Wm. Fox sends a "Field Mouse," and Mr. Crawshaw the "Head of a Salmon," illustrating the deterioration of the fish when caught too late in the season.

Illustrations of special processes do not abound. Messrs. Spence, Sawyer, and Bird send most magnificent examples of enlargement, both in landscape and portraiture, many of them simply perfect, both technically and pictorially; and their examples of photo-mechanical printing leave scarcely anything to desire. Their carbon prints in every form are also admirable: besides the numerous fine prints on paper, some examples on panel and canvas illustrate how perfectly the process lends itself to any form of work the artist in oil may require; and a little frame of miniatures on ivory, coloured and uncoloured, from negatives by Henna and Kent, show how admirably carbon printing serves the purpose of the miniature painter. The Woodbury Printing Company send examples of photo-relievo printing, which are absolutely indistinguishable from silver prints. Three prettily-finished "cretaceous photos," by W. Hanson, are effective. Mr. Vanderweyde exhibits some exceedingly fine examples of his mode of finishing, possessing fine artistic qualities. Mr. Werge shows the value of his method of adding artistic effect to a portrait by means of the "powder process," in a couple of prints entitled "Before and After" (116). Ceramic photography is not extensively represented; but Mr. Faulkner exhibits a few fine examples, as does Mr. R. Keene, of Derby. Mr. Spiller exhibits some illustrative examples of the photography of a by-gone period, which will be examined with much interest. The examples of statuary exhibited by Mr. England admirably illustrate the force, without loss of delicacy, which can be secured even in white marble by skilful treatment in lighting and manipulation; and Mr. S. Thompson's work of a somewhat similar character, ancient sculpture in the British Museum, is excellent.

The carbon transparencies of charming subjects in portraiture exhibited by Mr. Faulkner are very fine; as are also the transparencies by the Woodbury process. Mr.

York's transparencies are also very excellent. A series exhibited by Mr. F. Howard are delicate, but a little grey and weak. Mr. Ferneley and the Misses Davidson also exhibit good transparencies. Mr. Werge exhibits Howard's convenient tent and kit, and a mountaineer's camera and stand. W. H. Oakley and Co. send a universal tripod stand, with some capital convenient adjustments.

### PHOTOGRAPHING THE TRANSIT OF VENUS.

WE have been favoured by Mr. Glaisher with a sight of the singularly precise and clear instructions printed by the Government of the United States for the observing parties commissioned with the duty of recording the progress of the Transit of Venus. The carefully considered photographic operations will be found full of valuable suggestions, as well as matter of great interest. We have not space to reproduce the minute instructions for the pre-arrangement and adjustment of all the photographic apparatus, and the especial care to secure beforehand, not merely perfect focus, but perfect accuracy and parallelism, between the plate and the lens, and truth in the adjustments generally. The whole of the operations will be conducted with military order and precision, and perfect discipline maintained in the ordering and carrying out the duties and marking the rank and position of the various members of the party. Here are the specific instructions for photographic operations after the apparatus and photographic facilities of various kinds have been placed in position:—

After the photographic instruments are in place, the whole party must, from time to time, be drilled in the photographic operations. In the expenditure of material, care must be taken to leave plenty for two hundred pictures on the date of the transit. In this drill, the operations must be conducted as hereafter directed in the case of the transit, all necessary particulars must be recorded in the regular book, and the plates must be properly marked; but enough of the preliminary pictures themselves must be removed from the glass plates to leave two hundred plates for use on December 8-9.

On the morning of the transit the break-circuit chronometer must be brought into the dark room; the time by that chronometer at which the first and fourth contacts occur must be carefully computed; and the chronograph-key must be brought to the dark room and connected with the chronograph on which the clock or break-circuit chronometer must be recording its beats. The exact position at which external contact occurs must be determined from the angles hereafter given, and the sun's rays must be cut off by a shade between the slide and the plate, so as to admit only a small portion of the disc in the neighbourhood of the point of contact. A strip of the sun's edge one inch long by half an inch into the interior of its disc will be ample.

Immediately before the computed time of contact, the slide will be drawn back, and a sensitive plate will be placed, not in the plate holder, but in some moveable support immediately in front of it, and in such a position that when exposure is made the uncovered part of the sun's image shall fall near one vertical edge of the plate. An exposure will then be made, as nearly as practicable, at the computed moment of first contact; the plate will then be moved one inch, and a second exposure will be made, and so on to as many exposures as the plate will admit of. The chronometer time of each exposure must be noted and recorded, and the time must also be marked on the chronograph. To effect this, the key must be so arranged that the observer shall press it and release the slide at the same moment; and if the apparatus can be fixed so as to close the key automatically by the slide, it will be yet better. Each exposure on any one plate must be lettered in regular order, *a, b, c, &c.*, and these letters must be marked in the journal opposite the corresponding chronometer times.

The object of this arrangement is to have as many photographs as possible of the indutation made by Venus on the sun's limb during the first five or ten minutes of the transit. Therefore, while one plate is being exposed in the manner described, another must be preparing, so as to continue the process with the least possible delay. The exposures must be made as rapidly as the operations can be conducted, and the times recorded with the proper care.

The regular photographs of the transit must then be commenced. In the division of the labour of this important operation it should be the exclusive business of one person to see that everything is working properly, especially that the chronograph and heliostat are running, and that the latter goes at the right rate, and is not allowed to run down. The remainder of the force must be devoted to the

taking of the pictures and the record of the following particulars in proper ruled forms:—

1. A number, to be distinctly marked on each negative.
2. The chronometer time of exposure.
3. The reading of the level on the plate holder.
4. The direction (east or west) of the small arm on top of the frame, from the centre of which the plumb-line is passed through the plate holder.
5. The temperature in the room at the time of exposure.
6. The direction of motion of the slide (east or west).

In taking the pictures, the slide must be moved alternately east and west, and the direction of the arm carrying the plumb-line must also be frequently changed.

In developing the picture, the sharpest and best defined edge must be sought for, without regard to the details of the solar surface; and the image must be as dark as possible to the very edge. To attain this end, the central portions must be a little over-exposed. If the image is found to shade off toward the edge in any considerable degree, the time of exposure must be increased, first by widening the slit, then, when this is fully open, by lessening the tension of the spring. If the exposure is still insufficient, the slide must be moved over by hand with as uniform a motion as possible.

### OUTLINE OF THE PHOTOGRAPHIC PROCESS TO BE FOLLOWED.

*Cleaning the Plates.*—All the glass plates—seven by seven—are to be roughened on the edges with a sandstone and washed free from the grit. They are then to be immersed in dilute nitric acid, and left to soak for a short time. After being washed under the stream of water from a tap, and rubbed with a clean piece of cloth at the same time, they are to be set up in the frames provided for draining. As soon as nearly dry, they are to be thoroughly dried with a chamois skin and placed in boxes.

*Albumenizing.*—The glass plates are next to be albumenized. If fresh eggs can be procured, they may be used, otherwise the dried albumen must be taken. In the first case the white of one egg is to be beaten up thoroughly and mixed with sixteen ounces of pure water and filtered; in the second case, one ounce of the dried albumen is to be dissolved in sixty ounces of pure water, and after the addition of five drops of nitric acid is to be filtered.

The dry glass plates are to be flowed with this solution, taking care that none runs on the back, and set in the draining frames to dry. The edge of a glass plate may be used to assist in procuring an even coating. The photographic house previous to this operation is to be sprinkled, swept, and dampened again. As soon as the plates are dry, they are to be put into the negative boxes again. These boxes should be kept clean and free from dust and dampness.

The albumenizing is to be performed, if practicable, the day before the transit, and two hundred plates must be prepared. The boxes containing the plates must be labelled 1, 2, 3, 4, 5, and set in regular order on a shelf near the nitrate bath shelf. The chief photographer must, the day before the transit, number the plates with a pencil diamond on the back or non-albumenized side, beginning with number 1 on the left-hand side of box number 1, which should be at the left-hand end of the shelf as the operator faces the shelf. The object in view is to have the exposures made on a series of plates with consecutive numbers, so that a record may be kept in the book provided for the purpose, and accordingly the second assistant, who is to coat the plates with collodion, must be directed to take them out in succession.

*Collodion.*—The collodion to be used by the various parties must all be compounded on the same formula, in order to assist in securing uniformity of results, and to allow of a uniform method of reading the negatives. The formula to be used is—

Pyroxyline...	...	...	...	80 grains
Iodide of cadmium	...	...	...	96 "
Bromide of cadmium	...	...	...	8 "
Alcohol	...	...	...	9 ounces
Ether	...	...	...	8 "

In order to make the collodion fit for use at an early date, a few drops of an alcoholic solution of iodine must be added, so as to communicate a reddish-yellow tint.

The chief photographer is to make only such changes in the above formula as are absolutely necessary to adapt the collodion to the temperature at his station.

The process of flowing and its details are left to the discretion of the chief, it being understood that the main object in view is to secure a film without thick and thin parts, and one which will give the sun of as uniform density as the nature of his light will permit. A well marked outline must be obtained, and the central parts will necessarily be over-exposed, so as to show but little detail.

Collodion in sufficient quantity to coat two hundred plates must be prepared and tested several days before the day of the transit; indeed, this must be one of the first duties attended to on arriving at the stations. The collodion must not only be allowed to settle thoroughly, but must also be passed through the filtering bottles provided, and then put away in stock bottles. On the day of the transit both the filtering bottles must be filled and kept in that condition. All the plates must be coated from them.

**Nitrate of Silver Bath.**—The nitrate baths are to be composed of forty grains of nitrate of silver to the ounce of water, and are to be acidified in the proportion of one drop of pure nitric acid to four ounces of bath; three baths will be in use at a time. It will be desirable to use the purest water attainable; and if rain water, which has fallen on a clean roof at the end of a storm, cannot be procured, a sufficient quantity must be distilled in the apparatus provided for the purpose. In either case it will be proper to add to the water a small quantity of nitrate of silver and a few drops of ammonia, and set the mixture in the sunshine for several hours. A supply of water sufficient to make at least six baths must be ready for December 8th. A few days previous to the transit six baths must be made up, and tried with *plates which have not been albumenized*. It must be recollected that albumen has a tendency to injure the nitrate bath and cause markings on the plates, and hence fresh but still well-tried baths must be ready for the transit day. Such baths as have been used with albumenized plates may be utilized by neutralizing them with a small quantity of carbonate of soda, and setting them in the sunshine. They may subsequently be filtered and acidified. The baths are not to be iodized; they may be tested with litmus paper before use, and must present a well marked acid reaction.

**Developer.**—The pictures are to be developed with a solution made according to the following formula:—

Sulphate of iron and ammonia...	... 1 ounce
Glacial acetic acid ... ..	... 2 drachms
Alcohol ... ..	... 1½ ounces
Water ... ..	... 16 "

The exposure given by the sliding cut-off shutter must be sufficient to enable the above developer to bring out the picture in thirty seconds; and if the pictures are too feeble, the slit must be opened instead of increasing the time of development. The chief must modify the above developer to suit the temperature of his station, and must aim to get a sharp outline to the sun, and not a picture full of shading and details. He must take care that the image of Venus is not fogged to any great extent.

**Fixing.**—The fixing is to be done with cyanide of potassium solution in the proportion of one ounce and a-half to a quart of water. The plates made about the times of the contacts may be fixed with hyposulphite of soda in an india-rubber dish, so that the photographers may give all their attention to obtaining as large a number of photographs as possible at those times.

It is expected that during the transit at least one hundred and fifty pictures will be taken; but the photographers are directed to finish each picture and fix it before putting it on a draining stand. The only exception to be allowed is in the case of the contact pictures.

**Varnishing.**—After the transit is over, and as soon as the plates are dry, they are to be varnished in the customary manner.

(To be continued.)

## COMBINATION PRINTING APPLIED TO GROUP PICTURES.

BY E. RIEWEL.\*

IRRESPECTIVE of the question of art, the value of a group depends, in great measure, upon having all the portraits of the persons sharply in focus. How difficult it is to secure such a picture every photographer knows from his own experience. How frequently does it not happen that a photographer is compelled, after taking innumerable plates of an unsatisfactory character, to go back, after all, to the very first he has secured, which is perhaps successful enough, except as regards one of the models, who has moved. It is either necessary to do this, however unpleasant it may be to the photographer, or he must remain unrewarded for his trouble. The blurred image is retouched as well as possible, a task which, besides being unsatisfactory so far as the likeness is concerned, is, moreover, somewhat troublesome and costly. Another plan is to take the model that has moved over again, with a face of precisely the same dimensions, cutting out a proof on paper with a sharp and pointed knife; this excision is mounted carefully in its place upon a copy of the group, and the latter print, in a half moist state, is then put under a powerful rolling machine, the patch being afterwards retouched as well as possible. But such pictures as these do not appear successful unless they are covered with glass. A third method consists equally of taking the one who has moved a second time, separately, and stopping out the

negative except where the face of the sitter is seen. The group negative has a black patch where the face of the unruly sitter appears, and when a print has been secured with this negative the other one is put into the frame, and the face that is wanting is printed in. The manipulation of the negatives in this case requires some skill, for in the first place the spot must be accurately determined where the negatives overlap; and, secondly, the time of printing the face must be accurately estimated, for one cannot very well open the frame during the operation. This process has its disadvantages, for in winter time it is difficult sometimes to get the picture printed in a day.

Some little while ago I had occasion to take a group of a mother with three little children. In my first result it happened, as is often the case, that the oldest child was restless, while in the second picture it was the youngest that had moved. A third picture was altogether useless, because one of the children began to cry, and with this there was an end to any further attempt. There was no time for another appointment, for the picture was required for a certain occasion, and intended as a surprise. My desire to please, on the one hand, and not to be at all my trouble for nothing, on the other, caused me to examine the plates once more before destroying them, and I could not help thinking what a pity it was that the head in second plate did not happen to be in the first one. I resolved to see whether it was not possible to cut the head that had been well rendered out of the group, and transfer it to the latter plate, in which everything was satisfactory but the particular face. As a matter of precaution I first tried on the negative which had not succeeded so well. The experiment was successful; upon which I tried the other, and succeeded again to the best of my expectations. My simple plan of operating I will describe.

To protect the negative from injury—which, in the case of varnished negatives, is of course no longer necessary—I pour over the negative, after fixing and washing, a solution of gum in ten parts of water. When the film has dried, I take a graving needle and trace a line with it round the outline of the head, cut out carefully the bluntly defined spot with a knife, and coat the clear glass surface with a little gum solution. After I have drawn in like manner a line round the other head with the graving needle, I make a wedge-like incision from the head towards the edge of the plate, and endeavour, by means of a thin stream of water, to lift this portion of the collodion film, so that it leaves and swims off the film. Care must of course be taken that the head also does not slip away. When the head likewise begins to detach itself, I lay upon it a bit of wet filter paper, and commence to pull the film until I get it to the margin of the plate, when the latter is turned over, and I take the film and paper away. The film is now carefully laid upon the first negative, where the patch of clear glass is, some care being necessary to prevent the formation of air-bubbles; the film is pressed down by means of the filter paper, or smooth writing paper moistened with a little saliva. Any folds or creases in the film are removed with the aid of a moist camel-hair brush. Finally, the negative is varnished in the ordinary way, and the fissures in the film well retouched.

As the film of freshly prepared or intensified negatives with pyrogallic attaches itself more tightly to the glass than those treated with iron, it is necessary sometimes to moisten the plates first of all in acidified water, and then to employ a wash bottle. In transferring a large surface of collodion, I apply albumen, and find that the film then attaches itself very perfectly and uniformly. Albumen beaten to a snow, and then mixed with five-and-twenty times its volume of water, is applicable.

Some care and skill are of course necessary in the manipulations to which I have referred, if a successful result is required; and here, as in everything else, "practice makes perfect."

## Correspondence.

## COMBINATION PRINTING.

DEAR SIR,—In looking over some back numbers of the NEWS to day, I find that had I read that of August 21st as carefully as I am in the habit of doing, my letter in your paper this week would not have been written, and your valuable space could have been filled with more original matter.

Mr. Bovey's letter of that date, which I must have missed, contains, as your readers will see, the method of masking spoken of in my printed letter, and consequently I find myself in the position of having to apologise to that gentleman for appearing to claim his ideas on the subject of masking, with the additional mortification of feeling that Mr. Tilley still holds his secret.—I am, dear sir, respectfully,

Dunse, N.B., 23rd October. GEORGE BRUCE.

## ON THE EXTORTIONATE PRICES CHARGED FOR NOVELTIES.

DEAR SIR,—It is, I believe, an Englishman's privilege to grumble, so I offer that as an excuse for thus troubling you. It is not of business I am about to grumble, nor is it the price of chemicals, paper, &c., all of which are cheap enough; but I must enter a protest against the extortionate prices we are charged for any new thing. For instance, not long since I purchased a background, price £4 10s. Now I feel certain, on close examination of the article, that it could not have cost in its manufacture more than 30s. Then, again, recently I bought a cabinet size machine, price £5 (as uncertain in its operations as it is faulty in construction), which was made, I imagine, for about 10s or 15s.

Now, sir, there is profit! And this to be made out of us, who, I venture to say, labour against the keenest competition possible in a business. Whom the cap fits, let them put it on, as I, in conjunction, I am sure, with my brother photos., would like to see a few words in justification of charging such "fancy" prices. I enclose my card, and remain, dear sir, yours truly,

Plymouth, October 26th.

TAKEN IN.

## THE LAMBERT-TYPE PATENT.

DEAR SIR,—I was surprised and somewhat amused to see, under the above heading, a description of a method of finishing enlarged negatives which I have not only practised, but have given to the profession in my paper (read before the South London Photographic Society) upon enlargements v. direct large pictures. You say, in your leader, that Mons. Lambert claims as a distinct novelty the use of transparent paper upon both sides of a simply developed negative, and the working with pencils, or any other materials, upon both papers. It was exactly this point that I called attention to in the concluding part of my paper, and I exhibited a life-size head done in that way, which you were good enough to say was simply perfect. I was surprised that, in the discussion which followed, no one seemed to think this method of any importance, and so I let the matter drop, with the remark to a friend that if it had been patented, or sold as a secret process, it would have been appreciated.

I thought enough of it to continue its use, and work it out in my every-day practice; and the new mezzotint picture I have introduced is obtained by this method. The fact of its having been patented in this country, and your description of the results now exhibiting, may, perhaps, call photographers' attention to what is an easy and artistic method of finishing enlarged negatives; and although little, if any, attention was paid to it at the time I published it, photographers may congratulate themselves upon that publication, as that removes at once the patent restriction.

Yours truly,

G. CROUCHON.

[Mr. Croughton has, we think, slightly misunderstood our remarks. We have repeatedly spoken highly both of the method of producing enlargement which he published, and of the results. We do not now enter into comparisons of the relative advantages of the various methods, but there is a distinction, we think, between his method and that of M. Lambert. Mr. Croughton's special claim was, if we remember rightly, the production of an enlarged transparency, and producing the chief amelioration required upon it. From this he produced a still further enlarged negative, which might be again retouched if desired. In some cases he supplemented the enlarged negative with tracing paper, pointing out its special advantages for touching upon and softening the texture of strongly marked faces. The point of specific novelty which we indicated in M. Lambert's system was not the supplementary use of tracing paper, which we distinctly said had been used before; but the use of an image with no printing quality whatever, and—we quote our own words—"the systematic reliance on this method of treatment (the use of retouched paper) for all intensification and finish."—ED.]

## WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

SIR,—During the past summer several photographers have expressed a wish that a photographic society should be established in one of the large towns of Yorkshire, and, indeed, judging from the number that have signified their intention of joining, I presume one can be started enrolling not less than twenty-five members to begin with. Leeds, Bradford, and Halifax present a very creditable front in nearly everything connected with photography; and as Bradford is the centre, taking in these two towns within a radius of eight miles, besides innumerable other towns and villages that support quite an army of prosperous and clever photographers, why not resolve to have a start this next month, making that town the seat of photographic government for the West Riding?

I shall endeavour, with a few of my amateur and professional photographic friends, to galvanise the "Yorkshire West Riding Photographic Society" into existence by the middle or end of next month. I have already elected myself enrolling officer for Halifax, and shall be glad to hear from anyone willing to co-operate with me in Leeds, Bradford, and other places, or to be informed of the names and addresses of gentlemen desirous of becoming members.

I can speak of the enjoyable evenings profitably spent at the meetings of such societies, and cannot imagine an enthusiast in the art who would grudge a walk of half a dozen miles to attend the monthly meetings of one of them.—I am, yours, &c.,

J. W. GOUON.

Akroyden, Halifax, October 26th.

## Notes and Queries.

## IMAGE BEFORE DEVELOPING.

MY DEAR SIR,—I had not time to send you a line for insertion last week on the above subject, and the non-success of your correspondent "B. D.," related in your impression of October 16th. I have found in my experience as a dry-plate worker, that always, more or less, there is a visible image prior to developing plates organified with tannin, gallic acid, pyrogallic acid, ale, and morphia acetate, by reflected light—morphia especially; but I do not look upon it as a bad omen—quite the reverse. It is not to be seen so much in a plate that has been under-exposed, unless it has been left several hours before developing; then, only the sky is visible as a slight browning of the film by reflected light; the more the plate has been exposed, so in proportion, does the browning cover the plate. In the

appearance of an over-exposed plate, scarce any of the shadows are visible, and those that are, are slightly tinged with the brown hue similar to a print from a fogged negative. I prefer to see the image before developing, it being in my estimation the keynote to success, in proportion as the image is more or less visible; so do I understand how to modify the developer to ensure success.

In the fogging of a dry plate from over-exposure, and a wet one from the same cause, the behaviour of the former seems very different to the latter. The former, in some instances, seems to fog without showing an image, or very slightly; and the latter, one sees flash out and is gone as the developer covers the plate, and I think that is why many seem to be at a loss when attempting to develop a dry plate, however good they may be with the wet plate. My advice is, to novices with dry plates: do not attempt to go out with them until you are able to take a good negative at home with the plates you intend working. Thoroughly test them in this manner:—Expose one plate in the camera for a few seconds only (intentionally under-expose), and try to develop it; only the sky will appear, with the strongest high lights. Do not force development too much. Fix in the usual way, either with hypo or cyanide. The plate ought to come out perfectly bright, except where reduction has taken place (sky and high lights); if the plates are right, the rest will be bare glass. Expose a second plate, but this time with the intention to over-expose. Develop, and note the difference between the two plates. Reduction, in the latter case, has taken place over the whole surface of the plate, with scarce any appearance of an image. But if the first under-exposed plate is bright, it is a sure sign that the plates are all right, and success entirely depends on the skill of the operator, and not on the plates, whether prepared with emulsion or bath.

I think "B. D.'s" failure is from over-exposure. I have tried slow plates and rapid ones, but never found an ordinary plate that would allow sixteen seconds' exposure under a negative in a printing frame in the month of August; two seconds, or even less, would, I should think, be ample, and about five or six in the dull weather of December. I think if "B. D." tries again with short exposure he will be more successful. He must bear in mind that exposing under a negative is far different from the exposure in a camera, on account of the absorption of light by the lens, and its focal length must also be taken into consideration; whereas when a negative is employed in contact with the plate the amount of absorption is very small when compared with a lens at a distance in the front of the plate.

It is a great pity the Dry Plate Club was allowed to die out, where one could exchange valuable ideas with others personally working in the same direction.—I am, dear sir, yours very truly,

WILLIAM BROOKS.

9, Stratford Green, E., October 26th.

#### REDUCING EXPOSURE.

STR.—Photographers are promised "after a reasonable lapse of time" full details of Mr. Winstanley's method of reducing exposure in the camera. Those who are skilled in cryptography may possibly read the secret of the mystic letters and numbers before Mr. Winstanley gives the solution of his riddle. In the meantime I think it would be very interesting if your experimental correspondents who have worked in the direction of shortening exposure would state specific results. It was stated twelve months ago that Col. Stuart Wortley was making some successful experiments with the application of a reducing agent to the sensitive plate before exposure, so that the action of light and that of the reducing agent should go on together, *pari passu*. Has any detailed account of these experiments appeared? You have published from time to time promising accounts of the supplementary use of diffused light, and Mr. Samuel Fry some time ago gave most interesting details of his experience with the plan of using opal glass which you had just published. Have portraitists generally adopted this plan which was so highly avouched? Does Mr.

Fry continue its use constantly, or have drawbacks in its utility been found? I ask these questions in the interest of many of your readers, who, residing in country districts, have not opportunity of hearing the interesting but necessarily unreported photographic gossip of metropolitan life. Q.

#### IMAGE BEFORE DEVELOPING, ETC.

SIR.—Probably the real reason that "B. D." found the plates to fog in developing was that "Allsop" does not contain sufficient of the saccharine and extractive matter necessary to make the developer mucilaginous, these materials acting as restrainers, very much as bromide of potassium does in alkaline developing—indeed, quite superseding the necessity for it. The exposure for a transparency was at least eight times too long.

Depend upon it, "D. B.," that there is much more to learn in the developing of a dry plate than in the preparation of it. The visibility of the image may be due to 1st, a chloride being in the collodion; 2nd, over-exposure and the organic preservative—or both combined—but in every case over-exposure is indicated.

W. H. DAVIES.

#### Talk in the Studio.

MR. YORK'S TRANSPARENCIES.—We have been favoured by Mr. York with a copy of his new catalogue of transparencies for the lantern, containing his most recent additions to an already wonderfully complete collection, the novelties extending to subjects of interest as recent as the scenes of the gunpowder explosion at Regent's Park. The quality of these slides, we have before had occasion to describe as admirable, possessing the fine rich permanent black obtained by platinum toning. As Mr. York will send a specimen slide and catalogue for one shilling and sixpence, we strongly recommend all our readers interested in the lantern and lantern exhibitions to avail themselves of such a chance. The catalogue is the most surprisingly extensive and complete list of interesting subjects for the screen ever produced.

SCIENCE AT HOME.—Mr. Woodbury has just issued, in pamphlet form, some interesting articles he contributed to the *English Mechanic*, devoted chiefly to the exposition of a number of ingenious and clever lantern experiments, by which very charming and instructive effects may be produced. The book will be prized by all interested in the lantern.

PANORAMIC LANTERN SLIDE HOLDER.—Mr. Vincent Hatch sends us a copy of the provisional specification of a magic lantern slide holder for giving panoramic effects, which he thinks may interest photographers as the winter approaches. It runs as follows:—"The invention relates to improvements in magic lantern slideholders, whereby the slides are caused to travel in a continuous series slowly in succession past the opening opposite the lamp or other light employed for exhibiting the object or image depicted upon the slides, thus producing panoramic effects. The slideholder is so arranged and constructed that the top and bottom edges of the slides are retained in grooves or guides formed upon the holder, the slides resting in a vertical position upon and being carried by an endless band mounted on rollers attached to the slideholder or otherwise. The slides are introduced between the guides in succession, so as to be supported vertically end to end upon the endless band, to which motion is given by a crank handle upon the axis of one of the rollers or otherwise, by which means they are caused to travel slowly whilst the image or object thereon is exhibited in like manner to a panorama, as is well understood, or each successive slide may be kept stationary for a time at the will of the exhibitor. In the place of employing an endless band for carrying the slides they may be supported upon and carried by other forms of carriers in accordance with my improvements, such as a tape of worn fabric, leather, or other material wound to and fro upon rollers or other slides may be mounted upon carriers actuated by a rack-and-pinion or otherwise."

ACCORDING to the *Belgique Horticole*, Dr. Candèzi has invented a small photographic apparatus, which he calls a "scenograph," which consists simply of a stick and of a camera the size of an opera glass. To photograph a plant or other

object, it is sufficient to place it in the focus of the scenograph for a minute or two. The negatives [plates?], it appears, can be purchased ready prepared.

**WATERPROOF PAPER.**—The *Journal of the Franklin Institute* says that by plunging a sheet of paper into an ammoniacal solution of copper for an instant, then passing it between cylinders and drying it, it is rendered entirely impermeable to water, and may be even boiled in water without disintegrating. Sheets so prepared, if rolled together, become permanently adherent, and acquire the strength of wood.

**ENGRAVING ON COPPER.**—M. De la Grys reports a new process in the above named art, which consists in first covering the plate with a thin coating of adherent silver, which is, in turn, covered with coloured varnish. The lines are then drawn with a sharp point, after the fashion of using a diamond for stone engraving, and subsequently sunk into the plate by means of the action of perchloride of iron. A carbon print transferred to such a surface would render the engraving easy and the result accurate.

**PRODUCTION UPON WOOD OF PHOTOGRAPHIC PROOFS DESTINED FOR ENGRAVING.**—M. T. C. Rebo, in *Les Mondes*, describes a method. "The block of wood is first covered with a layer of gelatine (0.39 grammes to 31 grammes of water) by means of a soft brush. When this coating is dry it is covered, in the dark, with a solution prepared of:—1. Red prussiate of potash, 7.80 grammes; water, 62.20 grammes. 2. Ammonio-citrate of iron, 9.10 grammes in 62.20 grms. of water. These solutions are mixed and filtered, and the mixture is kept in the dark. When the layer is dry, it is exposed under a negative for ten to twelve minutes, and washed with a soft sponge, when a blue image appears. If thus prepared, the coating does not shell off under the graver."

## To Correspondents.

**PYROXYLINE.**—If you have, as you state, made pyroxyline for several years without meeting with such mishap as you describe, your experience has been very fortunate, as it is generally one of the earliest troubles of the experimentalist in this direction. The ebullition of the acids, accompanied by sudden evolution of red fumes, and complete solution of the cotton, is by no means uncommon, and may proceed from various causes. The proximate cause is generally excess of water in the mixture. The result may be brought about in various ways. Assuming that you commence with acids of the proper strength, and at the right temperature, the trouble may arise from placing too much cotton in the mixture. Having placed in the right quantity, you probably place in a tuft or two more, immediately upon which the ebullition commences. Or you may have failed to open the tufts of cotton sufficiently on placing them in the acid—a cause which will bring about a similar result. Or you may have failed to keep the cotton well stirred by means of the glass spatula, which will bring about a similar issue. The remedy to be applied on the first symptom is active, or even violent, stirring of the mixture, and the immediate addition of fresh nitric acid. The natural action on the generation of the red fumes (which are highly dangerous to health) is to rush out of the room, leave the mixture to its fate, in which case the whole of the batch is lost, as in your case. If you have energy and fortitude enough to take the steps we have indicated, you may speedily stop the ebullition and the discharge of red fumes, and save the batch of cotton with a comparatively small loss from complete solution, and the batch of pyroxyline gained will generally be of the powdery kind, suitable for many purposes. Should your hands not be covered with thick gauntlets at the time, you risk receiving severe wounds from the acid, which often spurts out during the ebullition.

**TYRO.**—The deposit on the plate sent is fog, proceeding probably from two causes: the use of a bath containing organic matter and probably insufficient acid, and the use of an imperfectly cleaned plate. The fact that the foggy deposit distinctly shows the circular markings caused by the final polish of the plate indicates beyond a question that the plate was not absolutely chemically clean, and probably slightly damp.

**T. E. LORD.**—The portrait of Jabez Inwards is in many respects good, but just a trifle hard. The strongly marked face and grizzled beard would have borne a little longer exposure to secure perfect softness.

**J. GLASSON.**—Newman's Manual of Photographic Colouring will answer your purpose. You will find details of enamelling in our last YEAR-BOOK.

**C. H. C.**—A further supply from America of Bigelow's Album is shortly expected.

**RES NON VERBA QUÆRO.**—The lens you mention may be used with a solar camera for enlarging purposes. The ordinary size of condenser used with a solar camera is nine inches diameter and eighteen inches focus. To work with the solar camera satisfactorily you will require an arrangement for moving the mirror so as to keep the sun on the centre of the lens. The solar camera, requiring absolute sunlight, is not the most desirable means of enlarging in a country like ours, where sunshine is rare and uncertain. You will find the method of producing a transparency, and from that an enlarged negative, a simpler and easier plan. You will find that method more than once described and discussed in the NEWS during the last twelve months. 2. Obscuring the glass on the south side of the studio will relieve you from the direct rays, and from the trouble of direct sunlight.

**F. H. W. B.**—The slight mottling in your prints is due to imperfect fixation in a very slight degree. Either the hyposulphite has been weak, or used to fix too many prints; or the prints have not been left in sufficiently long; or the prints have stuck together a little, not permitting the perfect action of the solution; or the temperature has been too low. In cold weather, the fixing power of the solution is very much reduced. You will notice that the mottling is generally in the skies and light parts of the picture, which have contained the greatest amount of unreduced chloride of silver, and have consequently required more solvent action from the hyposulphite to remove it. The prints upon which you ask our opinion are very good, but one or two of them would have borne a little longer exposure. The bare suggestion of a tint in the paper is not at all unpleasant. The condemnation of tinted paper to which you allude had reference to a direct and positive colour, which destroys the artistic quality of either landscape or portrait. There is no work devoted solely to landscape work. Mr. Robinson's "Pictorial Effect in Photography" is the best work to which you can refer. Some years ago there was a "Catechism of Chemistry" given serially in the PHOTOGRAPHIC NEWS, and subsequently reprinted in a little volume, which is now out of print. "Hardwich's Manual of Photographic Chemistry" is the only volume devoted essentially to chemistry in connection with photography. The older editions, now out of print, contain more chemical information than the last edition. If you could pick up one of the older editions, it would suit you best.

**B. F. R.**—We can only explain the issue of the erroneous announcements by supposing the error to have been an accident or oversight. Certainly they were without authority. No further prizes are announced, and there is no probability, at present, of any further renewal of them; certainly not for next year, we believe. **SPECIMENS WITHOUT NAME.**—Half-a-dozen card portraits, without name, are enclosed for our comments. No. 1 is good in many respects, but a little too low in tone; No. 2 is also good, but the partial vignetting is not well managed; No. 3 is flat from the presence of too much evenly diffused light; No. 4 suffers from the same fault, and is a little hard; Nos. 5 and 6—two portraits of a pretty little white dog—are good, and would have been much better if the focussing had been more careful; they both suffer from imperfect definition.

**N. T.**—So far as we know, the meeting of the Photographic Society will be held at the usual time and place: the second Tuesday in November, in the Architectural Gallery, Conduit Street. The exhibition will close next Thursday.

**PUZZLED.**—The term enamel has two applications in photography. Its correct application is to burnt-in or ceramic pictures; but the term enamelling is also used to describe the fine surface given to prints by a coating of gelatine and collodion. The latter process we have repeatedly described, as well as the former.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

LUYNES — CRAWSHAY — VOIGTLÄNDER — PHOTOGRAPHIC BOOK ILLUSTRATIONS—ARRIVAL OF THE TRANSIT OF VENUS EXPEDITION.

*Luynes—Crawshay—Voigtländer.*—During the Prince of Wales's recent tour on the Continent, he was the guest of an ancient family, whose name is still gratefully remembered by photographers even outside its native country. There is no worthier representative of the *vielle noblesse* throughout the fair land of France than the Duc de Luynes, and it is a name which the present generation honours, moreover, for the sake of what it has done for science and art. The present head of the family is but a child, for his father fell in the cruel war of 1870-71, in company with many other noblemen, fighting under a republican flag for their country's sake; the latter enjoyed the family title for two or three years only, but during that brief period proved himself a worthy scion of the family. As a traveller his fame is established, and as a photographer the world is to know more of him, for as our Paris Correspondent stated last week, a work is about to be published entitled a "Voyage in Syria" which will be illustrated by photographs taken by the late duke during his tour through that country. The photographs are to be printed, we are told, in fatty ink by the process of M. Negre, whose name as a photo-mechanical printer is already well known. The late Duc de Luynes' book will therefore be illustrated by means of a method the cultivation of which is due in a great measure to the encouragement given by his family; for it was for the purpose of inciting photographers to the working out of a photo-mechanical process, be it remembered, that the prize of ten thousand francs was offered by the grandfather of the present and father of the late Duc de Luynes, a prize which, in France especially, was fruitful in bringing forth many useful methods. It was this Duc de Luynes also, dying but half-a-dozen years ago, who devoted a large portion of his great wealth to the cultivation of the arts, a statue in solid ivory being one of the finest and rarest works produced through his munificence. As a man of science, and painter of no mean ability, he was one of the first to appreciate the wonders of photography, and was ever encouraging experimentalists in their endeavours to combine photography with the printing press. The prize of ten thousand francs was spread over two years, being divided by the judges into two awards, one of two thousand, and the other of eight thousand francs, the latter not being apportioned until twelve months after the first. The larger award, our readers no doubt remember, fell to the lot of M. Poitevin, as the originator of printing from colloid films, and we think that, on the whole, the award was a very just one. It is a singular coincidence that the amount of the Luynes prizes is about the same as that presented by Mr. Robert Crawshay, of Cyfarthfa Castle, the sums given by that gentleman falling little short of four hundred pounds. The circumstance is of course merely a coincidence, for it is not likely that Mr. Crawshay had the Duc de Luynes' gift in his memory when he made known his intention. France and England are not alone, however, in being fortunate to possess amateurs wealthy and generous enough to encourage photography in this way. Germany, too, in the person of Baron Voigtländer, has come forward nobly, and placed at the disposal of the Vienna Photographic Society funds for the purchase of gold and silver medals, to be awarded periodically, for the encouragement of the art. Having acquired a competence mainly through photography and photographers, he gratefully determines to do something for the art to which he owes so much. We repeat, may photographers long continue to honour the names of the generous trio, Luynes—Crawshay—Voigtländer.

*Photographic Book Illustrations.*—Two other journals have followed the example of the *Figaro Programme*, and present their readers with illustrations produced by photo-mechanical printing: one of them giving a Cabinet picture, and selling for sixpence, and the other (*The Stage*), published at twopence, containing a Carte print. All of these are produced by Woodburytype; but, judging from recent examples shown by the Autotype Company, and others who occupy themselves with the colloid process, the time is not far distant when we shall have illustrations in our periodicals of this nature. Meanwhile we hear rumours of a Christmas book to be issued, we believe, by Sampson, Low, and Marston, which is to contain a score of fine illustrations, Cabinet size, now being produced by the Photo-Relief Company, at Brompton, and which will most certainly be one of the best gift books of the season. It will be entitled "Beautiful Places," and the photographs will be twenty of the most beautiful scenes in the world, from Indian palaces to the snow peaks of Switzerland. We cannot help thinking that if this work is put properly before the public, it will place photographic book illustrations on a far more stable basis, and give them at once a more recognized position, such as they have never yet attained.

*Arrival of the Transit of Venus Expeditions.*—We are glad to hear of the safe arrival of several of the British Transit of Venus expeditions. Captain Abney, R.E., who had the shortest journey to make, and was, therefore, one of the last to start, has arrived with his party in Egypt. Lieutenant Darwin, R.E., who undertakes the photographic work connected with the party at Rodriguez, has also arrived at his destination. Captain Tupman and Professor Forbes are at Honolulu, and Major Palmer in New Zealand. Father Perry, who is in command of the expedition to that out-of-the-way place, Kerguelen's Land, has left Cape Town, and is, no doubt, also at his goal by this time. Mr. Gill, who is Lord Lindsay's lieutenant, has been at the Mauritius for some time awaiting the arrival of his lordship in his yacht, with the staff and necessary apparatus.

### ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

19. Coloured gases, whether elementary or compound—such as chlorine, bromine, and nitrous gas—have long been known to exert an absorptive action upon the luminous rays; † and their effect is not less marked upon the invisible prolongation of the electric spectrum.

The effects of the three halogens, chlorine, bromine, and iodine, in the form of vapour, are particularly remarkable. As a general rule, when a body exerts an absorptive influence, the absorption is greatest in the most refrangible portions; but the reverse of this occurs in the case of chlorine and of bromine. A column of chlorine two feet in depth cuts off the whole of the less refrangible portion as far as 143.5; beyond that a distinct impression is obtained as far as about 159. With bromine diffused in the form of diluted vapour the impression commences at 106, and is continued distinct, though rather feeble, to the extreme end of the spectrum. The apparatus required a slight modification to adapt it for the experiment with iodine. I used a glass tube six inches long, the open ends of which were ground flat so as to admit of being closed by thin plates of quartz; this was enclosed in a brass tube; a few grains of iodine were introduced, and the quartz plates fixed by metallic caps perforated to admit the passage of the rays; this tube

\* Continued from page 484.

† For an historical sketch of the progress of discovery in relation to the production of bands in the spectrum, the reader is referred to a paper by the author in the *Pharmaceutical Journal*, February, 1862, p. 17, *et seq.*

could then be supported as usual between the spark and the prism, and could be raised to and kept at a temperature beyond that necessary for the volatilization of the iodine. The electric light, after traversing such a column of vapour of an intensely deep violet colour, gave a strong spectrum, extending from 96.5 as far as 112, then it gradually faded till it disappeared at about 118; the impression became again rather faintly but distinctly visible at 142, and gradually disappeared at about 156. It is interesting to notice a somewhat similar interrupted absorption of the rays, though at a different part of the spectrum, in the case of the metallic iodides.

Both peroxide of nitrogen and peroxide of chlorine, in a stratum of two feet in depth, wholly absorb the chemical rays; but when more dilute or in shorter columns, they each give characteristic absorption-bands.

20. There appears to be little or no connexion between the absorptive power of any particular gas for the chemical rays, and its power of absorbing radiant heat as determined by the experiments of Dr. Tyndall.\* Aqueous vapour is highly diactinic, though not diathermic: olefiant gas exhibits a similar difference: and various other instances might be pointed out.

21. The most interesting fact, however, disclosed by these various experiments is the persistence of either the diactinic or the absorbent property in the compound, whatever be its physical state—a circumstance which proves that the property under consideration is intimately connected with the atomic or chemical nature of the body, and not merely with its state of aggregation.

The following diagram represents approximately the relative position of the portions of the spectrum transmitted in a few of the cases described in the foregoing section of this paper. No attempt is made to indicate partial absorption of the rays. In one or two instances, where complete absorption at a particular part of the spectrum occurs, this has been indicated by an interruption in the line.

§ 2. THE ABSORPTION OF THE CHEMICAL RAYS BY REFLECTION FROM POLISHED SURFACES.

22. In my earlier experiments I had much difficulty in obtaining a spectrum all the parts of which were even approximately in focus in the same plane, and, with the view of remedying this defect, I tried the effect of substituting specular reflection for the refracting action of a lens. This led me to compare the reflecting power of different polished surfaces for the chemical rays. With this object in view, a small polished plate of the material under

experiment was supported at an angle of 45°, as shown in fig. 3 (par. 6), opposite the vertical slit of the apparatus, so that when the source of light *e* was placed at right angles to the axis of the tube, the rays were reflected down the tube in the direction of that axis. The arrangement of the prism, lens, and camera was the same as that already described (6). As, however, much less light was reflected upon the prism from the polished surface than that which fell upon the prism when the direct rays of the spark were employed, the exposure of the sensitive plate in the camera was prolonged from five minutes to ten.

23. Among the metals and alloys thus submitted to trial were platinum, gold, silver, mercury contained in a trough with quartz faces, lead, copper, tin, cadmium, zinc, aluminium, steel, brass, and speculum-metal. In addition to these, the reflecting-power of quartz, window-glass, and Iceland spar was also tried.

No judgment of the perfection of the reflecting-power could be formed from the colour of the metal. Gold possesses the power of reflecting all the rays, even the most refrangible, very equally, though somewhat feebly. Next to gold ranks burnished lead, some part of the spectrum of the electric spark reflected from lead being more intense than that from gold. The length of the spectrum obtained from the light of the electric spark between silver points, by reflection from the surface of these two metals, extended from 96.5 to 170.5, or over the full distance of that obtained by the direct light of the spark, viz., 74 divisions of the scale which I have adopted. With all the other metals the spectrum of the same reflected spark terminated at 159.5, covering only 63 divisions of the scale.

The spectrum from a silver surface was remarkable. The impressed image was strong up to 112.5; then an abrupt cessation of the reflected rays occurred for a distance of 1.5 division; beyond this the reflection gradually returned, and continued tolerably intense till it reached 159.5, covering 63 divisions of the scale.

The reflection from mercury was weak in the middle, but strong towards each extremity. Platinum, zinc, and aluminium resembled mercury in their effects, but the spectrum was much less intense. The reflection from cadmium was similar, but still weaker.

The spectrum of the rays reflected from copper was deficient in strength for the last half of the more refrangible portion; and that of brass was similar to it, but weaker. The reflection from a surface of steel was more intense than that from any surface which I employed, but it ended abruptly at 159.5, or at the 63rd division of the scale. The spectrum reflected from tin was nearly as complete as that from steel.

A small concave mirror of speculum-metal gave an intense spectrum for the first half; but the more refrangible portion was deficient in power, and no rays were reflected beyond 159.5 (63 divisions), the point at which the other metals also failed. I therefore abandoned the attempt to substitute a speculum for the lens, with which latter I succeeded subsequently in obtaining a field sufficiently flat for the purpose.

24. The reflection from the surface of transparent objects was so scanty that, of course, no idea was entertained of using such bodies as mirrors; but it may be worthy of notice that a feeble spectrum was obtained from surfaces of quartz, window-glass, and Iceland spar, extending to 159.5, or over a length of 63 divisions of the scale—that is to say, fully as far as the majority of the metals. The quantity of the reflected rays was small, but its quality was similar to that of the rays reflected from metallic surfaces.

(To be continued.)

THE PRESS AND THE EXHIBITION.

The London Correspondent of the *Liverpool Daily Courier* has some appreciative remarks. He says:—

There is much to interest and gratify lovers of artistic photography

in this year's exhibition of the Photographic Society of Great Britain, which arranges its 466 exhibits in the spacious rooms in Suffolk Street, Pall-Mall. Portraits, choice landscapes, sketches of nature, animals, plants, and nondescript subjects are comprised in the varied collection. The competitive departments are particularly good, and local competitors stand well in the struggles after ideal perfection of sun-painting. The slow improvement of method achieves results which are more or less triumphs, in so far as they attain the charm of softness while maintaining clearness of form. There is a delicious gradation of shade in some of these specimens, which distinctly mark the advance made since photography has been taken up by professors imbued with a genuine sense of art. Mr. Robert Crawshaw, Cyfarthfa Castle, has again offered handsome prizes to stimulate competition in various branches of that art in which he is so successful and enthusiastic an amateur; and these competitions constitute the most distinctive feature of the exhibition, comprising as they do direct portraiture, enlargements, and landscape. Mr. C. Ferranti, Bold Street, Liverpool, obtains the Crawshaw prize (£25) for the best portrait enlargement, of which he shows four examples; and his success is the more complete as he does not contend in any other class, and has no failures to set off against his triumph. These enlarged portraits are so exquisitely artistic that an unprofessional critic would be rash to say which is most perfect of the four. The highest qualities one can perceive in photography are attained in Mr. Ferranti's delicate sense of finish. Mr. Crawshaw is himself a competitor in the class for seven-inch heads taken direct from life, and the judges have awarded him the second position—for of course he could not accept a money prize contributed from his own pocket. The landscape competition has produced some choice and charming examples, Messrs. Robinson and Cherrill, Tunbridge Wells, taking the first place. Messrs. Vandyke and Brown are of course represented in the exhibition, showing three half-length portraits in the class of direct enlargements, theirs being done on opal glass by development, very pleasing effects; and also three enlargements in carbon, slightly retouched. Mr. Young, Llandudno, sends very creditable exhibits in portraiture; and Mr. T. Edge, Preston, has a unique enlargement in—yes, in portraiture also, the "donkey that wouldn't go" being artistically represented caressing her foal.

(From the TIMES.)

Even with this, the nineteenth annual exhibition of the society fresh in one's recollection, we feel inclined to question whether the art—if it may not with more propriety be called the science—of photography is likely ever to become popular in that larger sense of the word which implies the favour of the people. It affords, indeed, occupation to a number of ladies and gentlemen to whose leisure hours amusement is more necessary than profit, and with this class, as we may gather from a list of the exhibitors in Suffolk Street, its popularity is undoubtedly on the increase. Popular, again, in one phase it is—that phase under which it was first introduced to public notice, and which lends itself only to the reproduction of the human face and form. To give and to receive "cartes-de-visite" is a favourite amusement with young men and maidens in every walk in life. In the old days, when portraiture was held as one of the fairest fields of the painter's art, this was an amusement beyond the reach of all but the wealthy. Not every man could go to Corinth in the days of Reynolds, of Lawrence, or of Gainsborough; but now, in these later times, the pencil of that more truthful, if less pleasing artist, the sun, is at the command of all; and where, from cottage to castle, may not be found some specimen of his handiwork? There is a charm, too, we admit, in the recollections of some happy time passed far away from the common places of our daily life which this art can keep green for us. A broken statue or moss-grown ruin, castled erag, or village inn, each and all may recall some memory which we would not willingly let die; while so far now has the photographer advanced on his onward path that the critic can enjoy equally with the traveller, nor need the pride of the eye be lost in the pleasures of memory. But photographs, we fancy, are never likely to become popular with that large section of the community who go to see pictures much as they go to the opera or to the park—because their neighbours go. In the first place, they lack colour—that is, colour in the broad acceptance of the term—and colour with these people covers a multitude of sins; even the most ignorant, to whom light and shade, perspective and drawing, and all the *argot* of the studio are but words and nothing more, can recognize the beauty of colour. Then, again, photographs *en masse* are, from the smallness and delicacy of their treatment, somewhat wearisome to those who are unable or careless to appreciate such subtleties; and, lastly, the chief charm of photography lies, as we have said before, in a previous knowledge of the subject not always to be found among those who visit picture galleries at this season of the year. But, with all this allowed, we advise all who can to devote at least some portion of these shortening days to a walk round the society's rooms. There are to be found in them all manner of subjects, taken by every process of photography known to man.

Portraiture, of course, is well represented, and well-known faces look down on you at every step you take. From loyalty, if from no

other motive, we may mention first an autotype enlargement of a portrait of his Royal Highness the Duke of Edinburgh (70), from the studio of Messrs. Spencer, Sawyer, Bird, and Co.; Mr. John Millais, R.A. (65), Miss Wallis as Amy Robsart (47), and Miss Neilson (17) are also there, in the same style and from the same hand. The fidelity of the likeness cannot be gainsayed, but whether that style of treatment is a pleasant one is, we think, a question which admits of more argument. At any rate, if we must have it, we prefer it when applied to inanimate objects, as the "Thames near Maidenhead" (62), "Ely Cathedral" (53), and the "Trout Stream" (219), all of which, and more especially the last, we are inclined to place above the portraits of the same artists. Mrs. Cameron sends twelve contributions, most, if, indeed, not all of them, portraits. This lady has deservedly attained a high reputation in her art, but we hardly fancy that the best specimens of her work are to be seen in Suffolk Street. Of the twelve, we like best a pretty picture of a little child praying at its mother's knee for the father's safe return (202). "Kiss me, Mamma!" (204), a portrait of Lady Hood and her daughter Mabel, is also pleasing, but Miss Mabel Bateman does not appear to advantage either as "Urania" (182) or Queen Henrietta Maria with her children (203). To the former is appended a quotation from "In Memoriam"—"Urania speaks with darkened brow"—and the aptness of the quotation cannot be denied, for the brow of Urania is so remarkably dark that it is with difficulty we can separate it from the background of flowing hair and the overhanging boughs beneath which Urania stands. Distinctness is surely one of the first essentials in a photograph. In large breadths of landscape and composition pictures this is a quality undoubtedly difficult of attainment with the camera, but we confess we should not be inclined to allow this excuse to portraiture. The colour in which photography appeals to the eye is not in itself pleasing, though, of course, this is far less apparent in some instances than in others; but when to this unmovable defect is added a slovenliness of execution—whether from accident or design—then, we submit, the photograph is lacking in one of the first requisites of good photography. There is, apparently, a growing tendency towards this style of work among amateurs which we fail to notice among their professional brethren, and it is on this hint we venture to speak. Three children's heads in one frame (330) from the same lady, though graceful in pose and in expression, are open, but in a less degree, to the same objection. Of all the portraits which have taken prizes in the Crawshaw Competition we like "The Gamekeeper at Home" (332), by Robert Crawshaw, best, though the judges have only awarded it a second prize. Passing to the landscapes, we find that our space will not allow us to say all that might be said on this head. They are as good as they are numerous, and though, where all are so good, comparisons might be spared, few will, we think, be disposed to deny the palm to Colonel Stuart Wortley. It is almost impossible to imagine photography carried to a higher pitch of perfection than in this gentleman's view of Carnarvon Castle (97), by the new uranium dry process, as the catalogue tells us. It has all the softness of a water-colour drawing, and, indeed, almost the colour, while the sky is as a sky of Turner's. "The Hill Side" (98) and "The Seint River at Low Water" (99) are good too, but not so good as this. Mr. Vernon Heath has two bits of Welsh scenery (79 and 80), and a view of Warnham Court (89), which fully keep up the reputation he has won. Mr. Bedford sends 12 charming little bits (20 to 31), of which we like the Welsh views best, and the "Declining Day" (278) of Messrs. Robinson and Cherrill might well have won the Crawshaw prize without its two companion pictures, "Repose" (276) and "Under the Greenwood Tree" (277) to help it. Mr. Sanderson also takes a prize with a view at Aberglaslyn (287), and Mr. Nicholson's "Valley and Pond of Bonehureh" (296) certainly deserves another. From the coast of Jersey Mr. Reuben Mitchell gives us some wonderful effects of threatening sky and sunset in 308 and 310, but the finest example of this most difficult study comes from Mr. G. Stodart, who in one frame gives us four instantaneous views taken at Margate (385-388), which are perhaps the most wonderful specimens of the photographer's art in the exhibition. In one especially, where the moon, breaking through a bank of angry clouds, shines down on a quiet sea, which scarcely ripples round the timbers of the pier, the effect is rather that of an etching than a photograph. Nor must we forget to mention a series of Indian views (417-448) from Colonel H. Dixon, which are even more soft and clear than the generality of photographs taken by the Indian sun. A dead stag (375), by Captain Horatio Ross, and a frame full of "Odd Dogs" (136), some of them very odd dogs indeed, by Messrs. Jabez and Alfred Hughes, will claim most attention from the lover of animal life. We have by no means exhausted our list of noteworthy objects, but we have, we trust, said enough to induce our readers to go to Suffolk Street and form an opinion for themselves.

#### PHOTOGRAPHING THE TRANSIT OF VENUS.\*

*Division of Labour.*—The duties of the photographers are as follows:—One of the assistants is to coat the plates, immerse them in the nitrate bath, and take them out when so directed by the chief. He is to be careful to preserve the order of the numbers. Another

\* Continued from page 525.

photographer is to develop the plates and fix them; the first operation, including the washing, should not occupy more than one minute, and the second a somewhat shorter time. A third is to take the plates from the assistant who coats them, place them in the exposure-frame, clamp them, make the electric signal, spring the exposure-shutter, note the time by a chronometer, take the number of the plate and the reading of the level and temperature, enter these and other particulars in the proper book, and hand the plates to the developer. The chief photographer must keep watch over his subordinates, and see that their duties are properly performed. He is to obey such orders about times of exposure as the chief of the party may give.

During the two or three hours of intermission between the optical observations already directed, either the chief of party or first assistant should remain in the dark room to oversee the operations, and should then, so far as possible, relieve the photographers of the duty of making the exposures and keeping the record, so that two of them may attend to the development and fixing of the plates.

The chief must also make arrangements to have a plentiful supply of water for washing on hand on the day of the transit.

#### SPECIAL DIRECTIONS FOR TAKING REVERSED PHOTOGRAPHS OF VERTICAL LINES OF PLATE-HOLDER.

1. Cover the photographic objective with a cap having a slit half an inch wide through its centre from top to bottom. See that this slit is truly vertical.

2. Cover one-half the plate with a screen fastened to it, and therefore turning with it, having one edge straight and vertical. This screen may be of yellow or black paper, entirely opaque to the photographic rays. The screen must be so arranged that when the plate-holder is reversed it shall cut off the rays of the sun which passed in the other position, and pass those which were before cut off.

3. See that when the plate-holder is reversed, the bubble of the level does not go to either end of the tube. If it does, the screw which adjusts the level of the cast-iron base on the pier must be touched until the bubble is in play in both the direct and reverse positions of the plate-holder. To do this it may be found necessary to adjust the level on the plate-holder; but this must only be done when absolutely necessary, and the fact of its being done must be entered in the journal.

4. Put a non-sensitized plate into the portable plate-holder, and put the latter into place by its guiding-pins.

5. See that the non-sensitized plate is parallel to the ruled plate, both in the vertical and horizontal direction. If not parallel, make it so by slightly turning the main plate-holder on its vertical axis, and adjusting the screw of the arm of the portable plate-holder. When parallel, the reflections of a candle from the non-sensitized plate and from the ruled plate will all coincide when seen through the flame of the candle itself from the back part of the photographic room.

6. Adjust the heliostat, and set it going, so that one-half the image of the sun shall be cut off by the screen on the plate-holder when exposure is made.

7. Replace the non-sensitized plate in the portable holder by a sensitized and albumenized one, and put the holder gently back into the position described in 4. Read the level, and make exposure. Owing to the covering of the objective, it will probably be necessary to move the slide by hand to get exposure enough.

8. The operator will then gently pick up the portable holder while an assistant reverses the main plate-holder on its axis, being careful to turn it exactly 180°. To indicate when to stop, suitable marks must be made.

9. The operator carefully returns the portable holder to the position described in 4 and 7, avoiding any jar which may change the position of the sensitive plate in the holder. The level is read, and exposure is again made, but not till the plumb-line has had ample time to come to rest.

When developed, the vertical lines should come out with all attainable sharpness and distinctness.

Always make the first of the pair of exposures in the direct position of the main plate-holder.

When satisfactory photographs are obtained in the manner described, put the screen on the other half of the plate-holder and repeat the process.

These reversed photographs must be taken on every sunny day during the month preceding the transit and the week following it. The set taken on each day must be accompanied by two photographs of the sun, showing the ruled lines, taken in the ordinary way without the screen, the arm of the plumb-line being reversed between the exposures. The level and the thermometer must be read in all photographs of the sun which are to be preserved.

#### DIRECTIONS FOR MEASURING THE DISTANCE BETWEEN THE OBJECTIVE AND THE PHOTOGRAPHIC PLATE.

The long rod, being in place as already described, must lie quite straight, in a line passing directly over the centres of the objective and of the plate-holder. The observer must sight along the rod to see that it is straight, and if it is not, the supports must be changed

to make it so. Then hang one of the fine brass-wire plumb-lines over each end of the rod, the bob hanging in a vessel of water. Take care that the outer bob is completely under water, so as to be protected from the wind. When the plumb-lines are at rest, press the arms of the jaw-micrometer against the edges of the object-glass, and by the two rack-motions bring the end of the central arm gently against the face of the objective, and the jaws into such position that the plumb-line shall be seen through and between the pin-holes. The plumb-line can be best seen through the holes with an eye-glass. In doing this, take great care to hold the micrometer horizontal. When all the adjustments are correct, read and record the vernier. When the measure is completed at the objective, pass to the plate-holder and take similar measures from the outside of the ruled plate. Each measure should be repeated several times by different observers, and each separate result should be recorded, with the initial of the observer, the temperature of the rod, and any other particulars necessary to a judgment of the observation.

Should the rod be too long, file a vertical notch on each side near one end, loop the plumb-line, and let it hang in these notches.

The distance between the surface of the ruled plate from which the measures are made and the collodion film when a picture is taken must also be repeatedly measured as accurately as the party is able to do it.

#### ON MAKING COMBINATION GROUPS.

BY B. J. EDWARDS.\*

In compliance with the invitation of our esteemed Secretary, I have to call attention to a method of making combination groups which is extensively practised in America. The plan is especially useful where a large number of figures are to form a group, and when it is only possible to obtain the photographs of the several members of the group by a number of sittings at various times.

In the first place it will be necessary to make a sketch of the desired group, introducing the required number of figures. The positions of the latter, and the general design of the group, may be varied to any extent to suit the subjects, taking care that the figures are drawn in true perspective, the front figures being larger than those in the background and middle distance. A suitable landscape or interior background is then sketched or drawn in black, and on a grey board, leaving space for the figures, which are lightly sketched in their proper places. A separate sketch is now made of each figure on small square pieces of tracing-paper; these little tracings are numbered to correspond with the figures in the sketch.

The separate figure negatives are now taken in the camera, the small tracings being held behind the ground glass to give the correct size and position of the figure. A print on albumenized paper is next taken from each negative, and having been carefully cut out, the figures are arranged on the background, and a reduced negative of the whole taken in the camera of the size required.

Some little care and skill are requisite to avoid showing the joinings. It will be found a good plan to bevel the edges of the prints from the back with a sharp knife. It will also be necessary for the foreground figure to be printed vigorously, those further back being printed more lightly, and sunned or toned down before being fixed.

Any little defect may be remedied or addition made with the brush on the finished picture. By this method groups of any number of figures may, with a little care and skill, be made in a very satisfactory manner.

#### AN AUTOMATIC, ECONOMICAL, SIMPLE, AND THOROUGHLY EFFECTUAL APPARATUS FOR REDUCING SILVER WASTES TO THE SULPHIDE.

BY W. T. BASHFORD.\*

FOR reducing silver wastes to the sulphide the advantages of sulphuretted hydrogen gas over sulphide of potassium are so well established that if a thoroughly satisfactory

\* Read before the South London Photographic Society.

\* Read before the South London Technical Meeting.

mode of using it were well known, it would, in all probability, be universally employed.

The delicate and complicated apparatus employed by the analytical chemist, from its expense and liability to injury, is unsuited to the uses of the photographer; yet, from the reducing agent being ready at a moment's notice, it has very great advantages. Mr. Foxlee has recently published in the *British Journal* a very simple means of generating the gas for photographic purposes, but his apparatus has the disadvantage of liability to breakage, and requires some time to put it into action, and after its work is done as much time is required to make it cease its action; it is also liable to waste the offensive gas by leakage. The apparatus about to be described has the advantages of the costly generator, without possessing the disadvantages of either machine. It consists of a stoneware cylinder about seven inches in length and about three inches internal diameter, furnished with a moveable perforated bottom, resting upon three shoulders placed about two inches from one end. The opposite end is closed to a small neck, perforated with a hole about a quarter-inch in diameter. To this neck is attached an india-rubber tube, with a pinch-cock close to the neck. The free end of the tube has a small piece of leaden pipe inserted into it to cause it to sink in the waste solution. The cylinder is filled to the shoulders with sulphide of iron in lumps, about the size of a hazel nut, and the perforated bottom is then placed *in situ* to prevent the iron falling out. The charged cylinder is now placed in a suitable jar (say seven inches deep

and six or seven inches diameter), and this jar is then filled with a solution of sulphuric acid one part, and water eight parts.

As long as the pinch-cock is closed, no action takes place; but the moment the pinch-cock is opened, the acid rises within the cylinder, and, acting upon the sulphide, immediately liberates sulphuretted hydrogen gas, which issues through the india-rubber tube. This action continues for any length of time, until its action is no longer required, when, by closing the pinch-cock, the gas stops flowing, and, filling the cylinder, expels the acid, which resumes its original position in the outer jar until it be again required, when at any moment a continuous supply of the gas can be obtained by simply opening the pinch-cock.

This automatic apparatus will be found inexpensive in first cost, extremely economical in use, is ready at any moment either to commence or cease its action, is not likely to get out of order or to receive injury, gives no trouble whatever, and thoroughly answers the purpose for which it is intended.

Lead may be used instead of stoneware, and a common gas tap may be soldered into the neck; but stoneware is preferable. If any one finds difficulty in procuring this apparatus, I shall be happy to supply a few similar to my own.

### Recent Patents.

#### SENSITIVE GELATINE PELLICLE.

BY R. KENNETT.

The following is the complete specification of Mr. Kennett's mode of preparing his sensitive gelatine pellicle:—

"The object of my said invention is the production of a new substance or compound to form an emulsion for photographic

purposes, and which, when prepared and sold in a dry or solid condition, will keep in this condition perfectly good for any length of time.

"My said improved substance or compound consists essentially of gelatine, or gelatinous matter, in combination with nitrate of silver, and with bromide of potassium, bromide of cadmium, bromide of ammonium, or with the chloride or the iodide of either of these salts in combination with either of the bromides above specified.

"In making the said compound, I prefer to employ the following materials and process—that is to say: I place in a dish or pan, of porcelain or other suitable material, about one pound of the substance known as Nelsou's gelatine, or other suitable gelatinous matter, to which I add about one hundred ounces of distilled water. This mixture of gelatine and water is allowed to stand for about three hours to soften the gelatine, and is then heated by a hot water bath, or otherwise, until the gelatine is thoroughly dissolved; I then add to the mixture or compound about eight and a quarter ounces of the bromide of potassium dissolved in water, and which must be thoroughly incorporated with the gelatine by stirring. I then incorporate with the said compound, while stirring the same, eleven and one-half ounces of nitrate of silver dissolved in water. The whole of the above operations must be effected while the gelatine is hot. At this stage of the process the said compound or emulsion will contain free bromide of potassium and nitrate of potassa, which must be eliminated, and which I eliminate as follows:—I pour the emulsion into glass or porcelain dishes to the depth of about a quarter of an inch, and let it stand long enough to become cold. I then remove it from the dishes, and cut it in small strips, and wash it with many changes of water, or in running water, until the free salts are all dissolved out. I then dry or desiccate the substance or compound, to render it capable of preservation for any length of time, and, therefore, fully accomplish the object of my invention. For this purpose I place the compound or emulsion in flat dishes, which are placed upon hot water boilers, or otherwise heated, until the said compound is reduced by evaporation to the consistency of a thick paste; then the said compound or substance is allowed to stand until it becomes cold. It is then removed by stripping it from the said dishes, and is placed, in suitable frames, in a drying closet, in which a circulation of dry air, either warm or cold, is maintained, whereby the drying or desiccation is completed.

"It will be seen, from the above description that the proper drying or desiccation of the compound is very essential to the success of my invention; but I wish it understood that I may employ any other suitable and convenient method of effecting the drying or desiccation of the compound instead of that above described. For instance, I may take the said substance or compound, after washing the same to dissolve out the free salts, and place it at once in the said drying closet; or expose it to an air blast, and thereby effect the drying or desiccation entirely without the application of heat. When dry, the said compound is cut into portions of convenient size, and in this condition will be ready for immediate use, or will keep perfectly good for a very long time. It may be conveniently made up into small packets for transmission by post to artists or amateurs in any part of the world. It is unaffected by changes of temperature or climate, and will render the plates to which it is applied highly sensitive, so that good pictures of animals, and other moving objects, may be easily obtained.

"The whole of the above described process for the manufacture of my new compound or substance must be conducted in a very weak non-actinic light. The quantity of gelatine used in the said compound may be varied to any desired extent; but the salts must always be in such proportion that there will be a slight excess of the bromide or chloride beyond its equivalent of combination with the nitrate of silver. Before its application to the plates, the said compound or substance must be dissolved in warm water, and it should be used in connection with the alkaline developer for dry plates.

"Having thus fully described my said invention, and the manner of performing the same, I wish it understood that I claim, a substance or compound for forming photographic emulsions which, when prepared in a dry or solid condition, as herein set forth, will remain perfectly good and fit for use for any required time."

### THE SOUTH LONDON TECHNICAL MEETING.

THE technical meeting of the South London Society has now become an annual institution, amongst the most instructive and interesting of the various agencies in existence for the advancement of the art. The happy conception, originally due to Mr. W. Brooks, has now acquired a definite form, and has, by judicious organization, become freed from the risks which last year threatened to render nugatory a good idea. The papers read, and the discussions which follow at ordinary meetings, have, beyond question, their specific value; and the occasional exhibition of novelties as an incidental element of such has always been interesting. But an unquestionable want existed which was not quite supplied by these means, nor by the annual exhibition of pictures by the parent society. Photographers required some opportunity for seeing many novelties and improvements of a technical character of which they had only heard, and of receiving explanations of—or, if necessary, brief discussions on—novelties they might have seen. Society meetings are not legitimate occasions for dealers to advertise their wares; but it may be frequently convenient for photographers, and legitimate for manufacturers, to exhibit and explain, under proper limitations, novelties and improvements of recent introduction. Photographers are often greatly indebted to the constructive ingenuity of some of their brethren for very valuable aids in the shape of improvised contrivances, and other technical improvements, for the introduction and explanation of which a meeting of this kind gives special facilities. The meeting is held, too, at some time whilst the annual exhibition is open, to enable visitors from the country to be present at both, a facility of which many country photographers availed themselves on Thursday evening. The amateur novelties shown were all singularly ingenious and useful, and the trade novelties interesting, and introduced without anything which the most fastidious could regard as "too much of the shop," the presence of which to some extent marred last year's meeting.

### THE PHOTOGRAPHIC EXHIBITION.

#### A FINAL GLANCE.

THE annual exhibition of the society closed yesterday, and has, we believe, in every way proved a greater success than could, under the circumstances, have been anticipated. The attendance has been good, and the financial results not much, we believe, below the results of last year.

A final glance at the contributions reminds us that there are many pictures worthy of attention which we have not had opportunity to notice, and some lessons to be learnt which might have been more fully dwelt upon. If the question of retouching had still been a moot point, we think that the results of the present exhibition would have tended much to confirm the position already accepted by most portraitists of position, namely, that moderate and legitimate retouching on the negative is desirable, whilst excess is destructive at once of the artistic and photographic value of the negative. In reply to the question as to what constitutes legitimate retouching, the answer is simple: the touchstone of legitimacy is success. Where the retouching is obviously obtrusive, where the texture of flesh is destroyed and that of marble substituted, where likeness or any natural truth is marred, the retouching is in excess, even if well done; it is always in excess when ill done. Some of the life-size direct pictures are very illustrative. Mr. Neilson sends three male life-size to the Crawshaw Competition, for which he deserves all honour. The work is, in many respects, very noble: well lighted, well posed, solid, and dignified. It is obviously quite untouched; there is a stern, rigid, Puritanic truth in it; but it is unlovely. Such pictures in black and white seem absolutely to demand some amelioration to bring them into conformity with the higher truth. The same is true of the grand female heads of Robinson and Cherrill. Last year this firm took the first prize; this year their photographic work is probably in no whit inferior to last year, but it is quite untouched; it sacrifices the higher artistic truth to conform to the literal standard of photographic truth. No one, we are satisfied, ever saw the faces of the models look so unattractive as the uncompromising camera has rendered them. In the next size—fifteen by twelve—the absence of retouching would have been much more tolerable; and Mr. Neilson has here, without touching, attained a very high degree of success; in "Reverie" and in "A Passing Thought" he has produced exceedingly fine pictures. Messrs. Robinson and Cherrill in that size have retouched a little, and obtained the prize. Mr. Crawshaw's own life-size heads were admirable examples of the refinement, without loss of truth or vigour, conferred by very little judicious retouching.

In the enlargements, with the exception of a fine collodion transfer by Mr. Palmer, we had no examples of untouched work: all the small negatives were obviously retouched in greater or less degree, and some manifestly in excess. The prints varied in degrees of finish, some being, apparently, untouched, whilst others were considerably worked upon. The prize enlargement, one of four very fine things exhibited by Mr. Ferranti, of Liverpool, was, besides being a very charming picture of a charming face, a fine example of the result of little work judiciously applied on the print. From a careful comparison of the prize picture with the small print and the unfinished enlargement, we find evidences of but very little retouching, the chief work consisting in giving a dull retiring surface to the background, and glazing the shadows of the hair, drapery, &c., to give them depth. In art the value of almost everything depends upon its relation to something else: force and relief for the figure are here gained by degrading the background; value and brilliancy are given to the lights by deepening the shadows. It is obvious that in pursuing this plan there is little tampering with the actual drawing and detail of the picture, and increased pictorial effect is secured without risking the loss of the likeness. Some very fine enlargements are shown by Messrs. Vandyke and Brown, finished, apparently, in a manner very similar to those of Mr. Ferranti, but suggesting somewhat more retouching. A beautiful female face, of winning expression, was very fine. Their enlargements on opal glass were singularly beautiful, and of admirable tone. A number of fine carbon enlargements, exhibited by the Woodbury Printing Com-

pany, untouched in the prints, but clearly touched at some stage in the negatives, were delicate and well defined, but they lacked force, modelling, and roundness; this lack probably being due to the original small negatives. Mr. Edwards exhibited several of his very admirable enlargements, admirable in all respects: well chosen subjects, fine small negatives skilfully retouched, and perfect enlargements. A pretty pensive female head, in profile, finely lighted (357), pleases us best, as besides the fine subject and skilful photographic treatment, it appears to illustrate the happy medium between too much and too little retouching. Least retouched, and exceedingly meritorious, amongst the enlargements, were those sent in too late for competition by Mr. Gillard; a few crisp touches on the negative would, however, have improved some of them.

Every term of praise for every quality desirable in enlargements seems to be fairly claimed, as we have said before, by the wonderful series of enlargements exhibited by Messrs. Spencer, Sawyer, and Bird; and as these are from negatives of all kinds produced by many different artists, and the excellence, as enlargements, seems to be pretty equal, the merit is manifestly due to the enlarging process and the mode in which it is worked. Indeed, nothing can more satisfactorily illustrate how much in successful enlargements is due to a suitable transparency (a point on which we insisted a dozen years ago) than this exhibition. Mr. Edwards produces a perfect albumen transparency, so delicate that the deposit rather resembles stained glass than the granular deposit of silver thrown down by development. The Autotype Company use a gelatine transparency prepared from a tissue of peculiar delicacy, and they produce a similarly perfect textureless transparency; and from these transparencies both succeed in producing enlargements which leave very little to desire. The "Trout Stream" in landscapes, a picture worthy of Salvator Rosa, and "Sunshine" in portraits, are singularly satisfactory examples.

Photo-mechanical printing is not extensively represented in the exhibition, the Woodbury Photo-Relief Process, and the Photo-Collotype Process, as worked by Messrs. Spencer, Sawyer, and Bird, being the only examples. Of the excellent examples of the former we have already spoken as almost, if not quite, indistinguishable in many cases from silver printing. The collotype examples of the latter firm appear more wonderful the more thoroughly they are examined. The architectural subjects, such as different views of the Norwich Cathedral, the Houses of Parliament, perfect as they are—and they are admirable—do not seem so trying a test as portraiture; but a frame of portraits, of some of which we have seen silver prints, are, if possible, more perfect. A curious opportunity occurs in one case of comparing two methods of permanent printing. In our last, in referring to some inaccuracies in the notice of the *Standard*, we said that they had attributed to the Autotype process some copies of Turner's *Liber Studiorum*, which were really by the photo-relief process. In this case we were in error: we had failed to observe at the time that a similar frame of copies from the *Liber Studiorum* were exhibited by Messrs. Spencer, Sawyer, and Bird, the latter being produced in two tints, a lighter and somewhat warmer pigment being apparently used for the middle and lighter tints, and a deeper colour for the deepest shadows, a plan by which force and delicacy are secured at once, the full value being given to the atmospheric tints in Turner's masterly work, without losing force in the foreground. The general tone reproduces the sepia tint of the originals more perfectly than the more foxy tint of the photo-relief prints, which are less harmonious than those in two tints.

There are various other contributions upon which we should have liked to make a passing comment if time and space permitted—Mr. Hunter's charming little cabinet groups, for instance: these have puzzled many visitors by

their resemblance to opal glass. We learn, on enquiry, that this is due to the paper prints being mounted in optical contact with the glass by means of clear gelatine. The delicacy, softness, and general fine qualities of the results of the gum-coffee process, as illustrated by the examples of Mr. Baynham Jones, were worth observation. The portfolio of exceedingly beautiful Javan and Indian views by Mr. Albert Woodbury, and the album of New Zealand photographs by Mr. Mundy, would require many columns to describe. Signor Ponti's album of direct life heads, with diagram and description of the novel camera in which they were produced, might have been described if we had space. But we must now perforce take leave of a very interesting exhibition.

#### "A HAPPY THOUGHT."

EVERYBODY knows that an evening exhibition of paintings is ordinarily a very unsatisfactory thing. Common gaslight fails to show the colours as they appear by daylight. The reason is obvious: gaslight is a very yellow light; its spectrum consists of red and yellow almost exclusively; the blue, as photographers well know, is almost totally wanting, and therefore, in pictures seen by gaslight, the yellows and reds are well brought out, while the blues and greens and all the tints containing blue are misrepresented. To remedy this defect during the evening exhibitions of "The Roll Call," which have just taken place in Newcastle, Mr. Swan suggested the employment of the lime-light instead of common gas, and the suggestion has been carried out with marvellous success, thousands of persons thronging nightly to see the famous picture, and expressing surprise and satisfaction with the effect produced by the novel mode of illumination.

Certainly it is no exaggeration to say that all the colours were as well rendered by the lime-light as by daylight. Two jets were placed in front of the picture, and nearly floor level, very much in the position of stage foot-lights. The jets were screened from the spectator by a draped barrier in front of the picture, and by a horizontal board extending from the top of the barrier half way across the space between the barrier and the front of the picture. A screen formed of a long strip of ground glass covered with white paper was placed in front of the jets, so as to cast its shadow upon the lower side of the gold frame, which, without this, was too glaring. The jets were inclined backwards. No doubt we shall soon have the idea utilized in the case of other pictures.

#### STRAY THOUGHTS SUGGESTED BY THE PHOTOGRAPHIC EXHIBITION OF 1874.

BY W. T. BOVEY.

ALTHOUGH photography no longer sparkles with the allurements of novelty, and familiarity with its products has, in some instances, transmuted former wonderment into something allied to contempt, its fascinating influence still clings to a host of ardent admirers, whose warm interest in the growth of the art finds vent in anxious enquiries relative to the progress it is making, as judged by an examination of the proofs now being exhibited in London. Does the exhibition, as a whole, give evidences of improvement? Is the mark of progression but doubtful, or is it unquestionably real? These and like queries rise uppermost in many a mind; therefore I need make no apologies for obtruding replies, more especially as I may conscientiously say yes to the first, again yes to the latter clause of the last interrogation. I cannot, certainly, point to anything sensational or startlingly original. There is an evenness which, in so decided a degree, I never witnessed before. The best men have not surpassed their former efforts; those who lingered in the rear are creeping slowly into the foremost ranks. The landscapes, as a rule, are more technically perfect; choice of subjects more artistic. Breadth of treatment has taken the place of former feeble

attempts to make things more pretty than real. In the place of those loud and badly selected skies once regarded as proper and fashionable, we notice that cloud subjects are thrust into their right places, and made subordinate to the remainder of the pictures, thus showing that photographers are gradually growing familiar with the rules of true art. If I were asked whether progress is more than moderately visible in any given direction, I would at once point to the Crawshaw prize heads and reply, "Yes: look you there! In lieu of those deep, heavy shadows, without transparency or detail; instead of those deserts of blank and broad patches, quite innocent of roundness and tone—defects too apparent in the large portrait work shown last year—we notice, in the present exhibition, faces so tenderly shaded that they steal softly from high light to shadow, and from shadow to high light again, without a perceptible break to show where either begins. Like elaborate mezzotint engravings, products of magical hands, these heads, as they hang in their frames, are proud examples of progress still going on. There is, however, more room for improvement: there is that something still wanting to awaken a semblance to life—that something which, absent, is missed by a critical eye. Those heads possess enough of technical perfection to credit their producers with gifts of remarkable talent. If genius would only give the last touches, tameness would give way, and there would be more of brilliancy and fire. I once heard Mr. Robiusion define this missing something as an absence of "pluck." This explanation, though rough, has the merit of being intelligible.

It is none of my duty to give special attention to this or that picture. Each exhibitor, doubtless, did what he could to excel; and many, at their best, have in some respects failed. To such I would say, *nil desperandum*. You will show something more perfect next year. But what may we say of those gentlemen who once were so zealous and true? Their absence this year breeds suspicion that missed prizes, if not absolutely the cause of this absence, have with it a great deal to do. I much fear that prize giving is like to prove a serious step the wrong way, and if persevered with will ultimately bring destruction on our annual treat. Egotism, jealousy, suspicion—these have already combined to blind the judgment of those who have tried and have failed, hence the reason why that so many honoured names may not be found in the catalogue of the present exhibition.

As human nature now acts, I see important objections to money prizes, or even medals being given. Indeed, I might with propriety write either down obstacles in lieu of an actual gain. Some few years ago I advocated the founding of an art union in connection with photographic exhibitions. The subscription for members a guinea per year. Tickets for the drawings one shilling. Each winner of a prize to select for himself from the saleable pictures exhibiting. If the picture chosen be of greater value than the prize won fully pays for, the difference might easily be adjusted, and so on. To each subscriber of one guinea the privilege of choosing a picture should also be given, or *pictures*, if the prices should be under the guinea. And to meet the necessary working expenses a fixed per centage should be required of each exhibitor whose works may be thus sold. If this or some similar plan were adopted, every photographer would have some fair prospect of being paid for his trouble; but as long as money or medal prizes are given, these must necessarily work mischief on account of their reaching the hands of but a few. It might be argued that prizes in any shape must fall into the hands of our best men. Truly; but who may decide which is best? The balance is often made to kick the beam on both sides by variations of opinion and taste.

By the way, I noticed in some of the enlargements examples of those "ropy beards," of which mention was made in a letter that appeared among the "Notes and

Queries." I have recently spent some considerable time in examining, with the aid of a powerful microscope, the peculiar construction of beard hair. On comparing this description of hair with that plucked from the head, I was surprised on observing the difference in structure; for whilst the latter is tubular and smooth of surface throughout, the former, near the roots, looks even enough, but from thence it grows flatter and rougher, and becomes quite jagged and uneven as it is seen at its ends. Not only are the peculiarities I have described clearly apparent, but there is an absence of those tender gradations of light and shade which belong to a cylindrical formation; hence the reason that the light line and dark borders when distended in the process of enlarging produce that ropy or mat-like appearance of which there is good cause to complain.

There are several other very interesting topics on which I intended to touch, but these must stand over just now. The winter and leisure, however, will enable me to write on, at short intervals, until the material I have had in store for several months is spun out.

### WASHED EMULSION PROCESS.

BY EDMUND PHIPPS.\*

THE following are the details of the method I have adopted in working the modification of the emulsion process suggested by Mr. Bolton, whereby washing and the use of a preservative are dispensed with—a rough outline of which I gave you at our last meeting.

Prepare a plain collodion of five grains of powdery pyroxyline to the ounce of mixed solvents, and allow it to settle for at least a week; carefully decant the required quantity, and add to each ounce seven grains of bromide of ammonium, finely ground into a little alcohol (this grinding is necessary, as the salt is but sparingly soluble in alcohol); well shake at intervals for about three hours; then add for each ounce fourteen grains nitrate of silver dissolved in the usual way in a little distilled water and hot alcohol. The proper equivalent of silver for seven grains of bromide of ammonium (the equivalent of that salt being ninety-eight) is a trifle under twelve grains. It is, however, desirable to have an excess to ensure the action of the silver on the pyroxyline. Agitate well for at least a couple of hours, and filter the emulsion in a dish set perfectly level; allow the emulsion to remain until it is thoroughly set, the time, of course, varying with the quantity used, the size of the dish, and the temperature. It should remain until it is capable of bearing a moderate pressure of the finger without breaking. When set, break up the film with a broad strip of glass, and wash slightly with distilled water. Transfer the film into a wide-mouthed jar, and well wash with many changes of ordinary water, smashing up the film into small pieces to ensure the *thorough* removal of all soluble salts. When this has been accomplished, and the water comes off clear, decant or draw off as much of the water as practicable, and wash again in three or four changes of alcohol; the latter having a strong affinity for water sneaks it out of the broken film. Finally: dissolve in a mixture of ether and alcohol.

The alcohol used for washing need not be wasted; it can be filtered back for future use. The alcohol used for final solution had better be absolute, to counteract the effect of any water left in the film. Ten ounces of plain collodion treated in this manner will yield about twelve ounces of finished emulsion. I do not add tannin or any other organic matter to the emulsion. If an ammonium salt be used in the collodion any amount of intensity can be obtained with the alkaline developer, and there is nothing to gain in this direction by organifiers. In the experiments I have made, I always found that the plain emulsion yielded better negatives than an organified one.

\* A communication to the Liverpool Amateur Photographic Association.

There is every reason to believe that an emulsion so prepared possesses indefinite keeping qualities. The negatives I have here to-night were taken by an emulsion prepared in the manner I have described on the 12th of August last; the plates were prepared, exposed, and developed two or three days since. The emulsion is quite as good as when first prepared.

To prepare the plates, albumenise with dilute albumen (one to twenty of water), back with burnt sienna, and, when thoroughly dry, coat with the emulsion and set up to dry. The drying may be by heat or spontaneous; it makes little matter which method is adopted. The exposure is decidedly rapid. With a Ross's medium-angle doublet of seven inches equivalent focus, largest stop, and well-lighted landscape, forty seconds will be about the exposure. However, great latitude is allowable; for, by the method of preliminary treatment with pyro, it is possible to judge of the correctness or otherwise of the exposure with great accuracy before the real development begins.

To develop, pour over the film undiluted alcohol of average strength, wash well, and pour over a four-grain solution of pyro (see that there is no trace of alkali in it). Now carefully watch the plate. If properly exposed, the high lights and the secondary lights will appear in about half a minute. A very little experience will soon enable the operator to judge as to the exposure, and adapt his developer accordingly. Assuming the exposure has been correct, to a three-grain solution of pyro add one minim of a ten-grain solution of bromide of potassium, and one minim of dilute ammonia (one part of ammonia to eight of distilled water). Treat the plate with this until its power seems exhausted; then add another drop of the ammonia solution, then a drop of bromide and a drop of ammonia until the details are all out, and the plate sufficiently intense, no large addition of ammonia being made without bromide to check it. The first application of the alkaline developer must have a trace of bromide, or fog will ensue (see also an excellent method described in the *British Journal* for July 17). If, by the preliminary development, the plate appears to be under-exposed, use the strong alkaline developer; but be cautious not to push it too far, or the image may be over-intensified. If over-exposed, use an excess of bromide and very little ammonia, and, if necessary, intensify with acid silver; or, if much over-exposed, push the development with the plain pyro until all the details are out, and intensify with acid silver without using the alkaline developer at all. Intensification with silver will rarely be needed unless the plate be over-exposed. If it be, however, necessary, use it before the film is allowed to dry. The plates are also capable of being developed with iron, a wash of nitrate of silver solution being applied before the developer is used. Fix with hypo in the usual manner.

The numerous advantages of the process to a dry-plate worker, to amateurs especially, are so patent that any comment by me is unnecessary. I would only observe, that from the very nature of the process, it possesses in an extraordinary degree that quality which, of all others, is so essential in a dry process, namely, uniformity and certainty of result. I trust that others may be induced to experiment and make known their experience, with a view of rendering the process as perfect as possible.

### Correspondence.

#### RE-ESTABLISHMENT OF THE PHOTO. EXCHANGE CLUB.

SIR,—I have a number of large negatives, up to twenty inches, of Welsh and other scenery. I should like very much to exchange prints with some photographer upon the same terms as those framed by the members of the Exchange

Club in existence some few years ago. Could it not be re-established? I am sure by this time many amateurs would be glad to do the same.—Yours, &c.,  
EXCHANGE.

#### KENNETT'S PELLICLE.

SIR,—No doubt many of your readers will be glad to hear of any experiments with the above dry plate process, so without any further preamble I will state the result of my first attempt.

I felt perfectly satisfied with the results Mr. Kennett was kind enough to show me, both as regards the negatives, and prints taken from them. I was only anxious to test the "pellicle" for rapidity. I first took a group out of doors, in the middle of last month. The morning was not very bright, although the sun was shining through thin clouds. The lens used was Dallmeyer's No 2B, with No. 4 stop. I first exposed one of the "quickest commercial dry plates in the market," giving an exposure of three seconds for one picture, and five seconds for the other. I then exposed a plate coated with "Kennett's pellicle," allowing two seconds' exposure on each picture. These plates were developed the following day. The first named plate had not received sufficient exposure by a long way; eight to ten seconds would have been nearer the mark. The "pellicle" was amply exposed. On another occasion I tested the sensitized gelatino pellicle against a wet plate in my glass room, in which there is never such a flood of light as one commonly sees in most photographic studios. I gave ten seconds to the pellicle, and twenty-three seconds to the wet plate, using the same lens as before, with No. 2½ stop. Both negatives were sufficiently exposed.

I may add that on the same day that I took the photograph of the group out of doors, a friend of mine was taking negatives on the wet plate process, under similar circumstances, with a Ross's C.D.V. lens, 2½ stop, and that the exposure necessary was sixteen seconds.

A PORTRAIT PAINTER.

### Proceedings of Societies.

#### SOUTH LONDON PHOTOGRAPHIC SOCIETY. TECHNICAL MEETING.

THE technical meeting of this society, in accordance with announcement, was held in the Cambridge Hall, Newman Street, Oxford Street, on the evening of Thursday, the 29th ult., the Rev. F. F. STATHAM, M.A., in the chair, when a full attendance of members and visitors was present. After a few introductory remarks, explanatory of the purpose of the meeting, from the Chairman, the Secretary read the minutes of a former meeting, which were confirmed.

Mr. HUGHES then proposed a vote of thanks to Mr. Samuel Fry for his kind invitation to the members to visit his landscape studio at their open-air meeting, and for the handsome entertainment they received. The motion was carried by acclamation.

The following gentlemen were then elected members of the society:—Messrs. Tench, J. C. Heavyside, C. Ferneley, J. M. Nisbet, Prestwich, Herr Warnaeke, and Signor Fanchoni.

The CHAIRMAN read a letter from the Secretary of the Belgie Photographie Society at Brussels, enclosing the first two numbers of the *Bulletin* of the society.

Mr. W. T. BASHFORD sent a brief paper describing a simple method of generating sulphuretted hydrogen gas for reducing silver wastes, and exhibited the jar described (see p. 532).

Mr. HUGHES, in a few words, explained the action of the apparatus.

The CHAIRMAN suggested making the base of the jar wider and heavier, to prevent the risk of its being overturned, and so causing an escape of the offensive gas.

Mr. SEBASTIAN DAVIS suggested the necessity of some method of securing escape for the gas as rapid as the generation, to prevent a similar risk.

A Member proposed that the chamber at the bottom of

beneath the sulphide of iron, should be larger, which would aid in preventing risk of escape of the gas.

A universal tripod stand, by W. H. Oakley, was exhibited and described by the Secretary as follows:—

"The top is triangle, and has three adjustable sliding legs, held firm by thumb-screws, which, by loosening, will allow the sliding legs to be set from the smallest possible adjustment or angle, and from three feet to five feet six inches high, and by tightening the screws is as firm when at its total height as when down (thus remedying the great fault in all other stands), and, being so easy of adjustment, will be found just the stand needed for out-door and indoor photography and exhibition, &c.

"It is invaluable for taking interiors on stone pavements, as they can be made rigid by tightening the thumb-screws, and when once set level will remain so; can be set to any height to suit the subject; and set level upon any uneven place—for instance, side of a hill, roof of a house, &c.; in fact, there are so many advantages, that a sight of the stand or drawing will show that it is just the stand needed.

"A ball and socket joint is also fitted, if required. Its advantages in many instances, for photography, &c., will be seen at a glance; the top can be set and held by the screw under triangle to any angle either way, or can be shifted round to follow up any passing object, &c., without moving stand.

"It has been used for taking views of ships in motion, and also the animals in the Zoological Gardens, and for such uses it will be seen to be of great service; thus, as the animals have to be taken just as they are, in a state of rest or ease, now the ball and socket arrangement will allow the camera to be shifted round as the animal moves from place to place, and when a moment still, the photo, taken. Also, as the ball and socket is made of box-wood and brass, and made to fit well, it will not allow the camera to slip unless the screw underneath is loosened.

"They are made in various sizes."

Mr. HUGHES, commenting on the conveniences and utility of the arrangement, remarked that the principle was an old friend, having been used by photographers five-and-twenty years ago.

Mr. TULLY, after asking the meaning of the word "copyright" appended to some prospectuses of the stand, wished to protest against the tendency to pooh-pooh inventions, and deny their novelty.

The CHAIRMAN thought Mr. Tully misunderstood the temper of the meeting. The very fact of such a meeting being held was proof of their wish to give publicity and credit to every invention. It was a simple matter of justice, however, to point out the fact of prior invention or discovery of a similar contrivance.

Mr. SAMUEL FRY exhibited a fifteen by twelve negative, produced on the afternoon of a dull day with a Dallmeyer 5D lens in forty seconds, the plate having had a preliminary exposure through opal glass of about ten or fifteen seconds. Without this treatment the necessary exposure would have been about three minutes. The principle of pre-lighting which he had before brought before the society had not, he thought, yet received sufficient attention or trial. He had noticed that, as a rule, those who had tried the principle, and failed in getting satisfactory results, had not carried out the principle properly, but had adopted some method different to that which gave success. In one case a gentleman who had failed, instead of placing opal glass in front of the lens, had placed it inside the camera in front of the plate. The plan by which he himself had succeeded consisted, as he had before explained, in having a cap for the lens, consisting of a wooden rim with a disk of opal glass. The plate being in, the camera received the light through this opal glass for a certain time, which must depend on circumstances, being carefully adapted to the character of the lens and of the light, and this could only be satisfactorily ascertained by trial and experience. If the plate fogged, the time of pre-lighting was too long; if no palpable advantages were gained, the time was too short. The same principles were in operation when a light background was used. He had found that on using a dark background a much longer exposure was necessary, whilst with a light background which reflected a certain amount of light into the camera, a good harmonious negative could be obtained with an exposure altogether insufficient when a dark background was employed.

In answer to a question as to the ratio of reduction in exposure on using the opal glass, Mr. Fry said that as a rule fully half the ordinary exposure might be given.

Mr. HUGHES asked if this were at the sacrifice of any brilliancy or excellence of any kind in the result.

Mr. FRY: There is no loss of any kind. If the time were properly adjusted, the negatives were in every way as perfect.

Mr. B. J. EDWARDS asked whether, in using a light background the advantage was due to the light reflected, or to the modified deposition of silver in development, the light background attracting more silver than the dark, and so preventing the risk of hardness.

Mr. FRY had not carefully examined that point, but believed it due to the light.

Mr. SAWYER said that at the Autotype Works they had tried pre-lighting in copying large pictures usually requiring from ten to twenty minutes' exposure. They had tried various times of preliminary exposure—five, ten, fifteen, twenty, twenty-five, and thirty seconds—and in every case where any result was perceptible at all, it consisted in more or less fog. Sometimes an apparent advantage, on examining the negative, was gained; but the best printing results were invariably obtained without the pre-lighting. In the matter of backgrounds, his own experience was, that where other things were equal, a dark background gave the best results.

Mr. FRY thought it quite possible that pre-lighting might be no advantage in copying. As regarded the background question, he could simply repeat that, after many comparative experiments, he had always found a light background give the best negative with the shortest exposure.

Mr. BLANCHARD had found that, under certain conditions, a decided advantage was gained by the preliminary exposure. It was a thing well known to old Daguerreotypists, and he had used it twenty years ago. He then proceeded to relate a conversation between himself and Mons. Adam-Salomon, and an experiment they tried in photographing a bronze and a marble statuette side by side. An exposure of five seconds gave an image in which the white had no detail in the lights, and the bronze none in the shadows. They tried again with the same exposure, then, closing the lens for a moment, removed the bronze statuette, and exposed for a few seconds against the background alone; the result, on developing, was an harmonious image of each. He had found the preliminary exposure of very great advantage in dull winter weather, whilst in the bright light of summer it seemed of no use. For use with slow lenses in bad light it was extremely valuable, and gave that quality which photographs often so much lacked, and which was of such art value—harmony in the picture.

The CHAIRMAN regretted that they had not time to pursue the discussion further at that time, but suggested that Mr. Blanchard should prepare a paper on the subject for a subsequent meeting.

Mr. B. J. EDWARDS showed some exceedingly perfect transparencies and enlarged negatives produced from them, and also read a brief account of a method of producing combined groups (see p. 582).

Mr. WERGE exhibited some fine negatives and prints illustrating the results of his method of producing pictorial effects on the backgrounds of old negatives by the "powder process," the details of which have been already placed before our readers. Mr. Werge also exhibited and explained the advantages of a shutter inside the camera for covering and uncovering the lens, instead of using the ordinary cap.

Mr. HUGHES said he had had a similar shutter in use for twelve years, and was surprised that portraitists should continue the use of the clumsy cap, the removal of which from the lens always distracted the attention of the sitter, and produced that rigid, unnatural look which came with the consciousness that the operation has begun, whilst a simple easy plan was available which was free from all the objections and drawbacks of the cap.

Mr. HUNTER showed a plate-box for conveniently carrying a store of plates or negatives.

Mr. WERGE exhibited and explained the action of Westou's Burnisher.

Mr. BERTIN exhibited a convenient filter for collodion, similar in principle to Maynard's collodion filter described in our volume for 1872. It permits collodion to be filtered without evaporation, the upper vessel being properly stopped, or corked, an india-rubber tube connecting the upper vessel with the lower vessel, so that the air displaced from the lower vessel passed into the upper vessel, and so maintained the flow of the collodion. He also exhibited a double filter, a space existing between the inner funnel and the outer funnel, by which the clogging and slow filtration often experienced was prevented.

Mr. BERTIN also exhibited a very clever and convenient adaptation of the old well-bath fixed in a cradle and case with lid opening in front. The plate was placed on a ledge in the bath whilst in an upright or sloping position, the lid closed, and the bath tilted by means of the cradle, into the horizontal position, and so covered with the silvering solution.

The same gentleman also showed a simple and convenient method of fixing blotting-paper in the corners of the dark slide, a groove of about one-sixteenth of an inch or less wide, and an inch long, being provided at each corner, into which a piece of folded blotting-paper was placed and easily held firm.

Mr. HARRISON exhibited an arrangement for using an improvised paper dish for developing purposes. It consisted of four pieces of wood planed square, about a foot long, and an inch or less in each diameter. These were mitred at the corners so as to form a frame, and hinged with bits of string tied through three of the mitres, the fourth being fastened by an india-rubber band. A piece of paper being folded with edges turned up to form a dish, each corner was placed within the opening of the mitres, and the frame fastened with the india-rubber band, and these formed a perfectly firm dish. Waterproof paper might be used, and each dish thrown away when done with.

Mr. DAVIS spoke of the advantages for developing dry plates, there being no possible risk of lurking contamination in the corners, a constant risk with ordinary dishes carelessly washed.

Mr. HOWARD suggested using parchementized paper, and

Mr. BLANCHARD suggested varnishing paper with a mixture of collodion and linseed oil, which he had found admirable for such purposes.

Mr. CUSSENS showed a convenient developing holder.

Mr. MIREX showed a zinc plate-box with wire grooves.

Mr. ATTWOOD showed a convenient printing-frame.

Mr. KENNETT showed some negatives, transparencies, and prints, illustrating the working of his gelatine pellicle.

After some remarks by the Chairman and by Mr. Hughes, and a vote of thanks to the exhibitors and the chairman, the proceedings terminated.

#### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held on Tuesday, the 27th ult., at the Free Library, William Brown Street, the Rev. H. J. PALMER, in the chair.

The minutes of the former meeting were read and passed.

The CHAIRMAN handed round a number of fine negatives with their corresponding prints. The negatives were by Mr. Penny, of Cheltenham, on plates prepared with Mr. Kennett's gelatine pellicle. They were excellent examples of the capabilities and rapidity of the gelatine process, most of them having been taken with an exposure of five seconds and under. He also handed round some negatives of his own preparation by the same process. He (the Chairman) had (owing to the effects of the ether in collodion on his health) determined to abandon its use, and, if possible, work only with the gelatine process. For some time he had met with nothing but failures for which he could not account. He had, however, at last succeeded, and he could strongly recommend the process. One of the great causes of failure was that his plates were mostly fogged. He got rid of this by using two thicknesses of orange tissue paper over his orange dark-room window. Spots on the film were another cause of failure. These were avoided by taking care, in returning the excess from the plate to the bottle, to pour it down the side of the bottle, and not to allow any bubbles to remain on the coated plate. In coating, the film ran more easily and lay more evenly by first breathing on the plate. Taking care to follow the directions given by Mr. Kennett with each packet of pellicle, and keeping down the light (for the plates are exceedingly sensitive) he felt sure that anyone with care could succeed with them.

Mr. J. H. ELLERBECK handed round some sheets of coloured gelatine, which he found very useful in using in addition to his usual dark-room glass.

Mr. ATKINS exhibited a film negative, detached from the glass, and explained the advantages of being able to print from either side of the negative.

The Secretary read a letter from the President of the Belgian Photographic Association, and handed round the first and second number of the *Bulletin*, issued by that Association.

The CHAIRMAN said he was sure that the members would join with him in wishing success and prosperity to the new society, which, he was glad to see, had been formed in Belgium to extend the popularity of their delightful art.

Mr. E. PHIPPS then read a paper on the "Washed Emulsion Process" (see p. 536).

Mr. PHIPPS stated that he found the process was much more rapid than the ordinary bromide process. He usually allowed the plates to dry spontaneously. There was great latitude in exposure, and if it was expected that too long an exposure had been

given, it was advantageous to let the bromide of potassium and pyro developer soak well into the plate before adding the ammonia; indeed, sometimes the development could be obtained even without ammonia. It was also advisable, in case of re-developing after the plates had been dried, to first moisten the plate with spirit to thoroughly soften the film. Reference having been made to the use of ammonium bromide, he (Mr. Phipps) stated that with cadmium he was not able to get sufficient printing density, and it was only when he began to use ammonium first in conjunction with cadmium, and subsequently alone, that he obtained anything like a good negative; he was confirmed in his opinion of the value of ammonium by observing that Mr. Stillman, in his published formulæ in his handbook for amateurs, used bromide of ammonium only, to the exclusion of cadmium.

The meeting was shortly afterwards adjourned.

## Notes and Queries.

### PRELIMINARY LIGHTING.

DEAR SIR,—I have much pleasure in replying to the inquiry in your last whether I use the opal accelerator in my portrait work. I beg to say that during dull weather I never take a picture without. I had this day to take 12×10 portraits in a very bad light; but with twenty seconds' pre-lighting and seventy seconds' exposure very fine negatives were obtained. Convincing evidence was given of its value by the fact that having been forgotten for one picture, the result was a totally useless negative from under-exposure. Mr. Blanchard justly said, in reply to a query at the South London Technical Meeting, that "you may call it fog, or by any other name you like, but it is a good result."—I am, respectfully,  
SAMUEL FRY.

### "SPECIMENS TO BE SENT."

SIR,—Can any of your readers suggest a remedy for an oft-repeated wrong? About a month ago I answered an advertisement which appeared in your journal with the usual announcement, "specimens to be sent." I complied with the request, and forwarded a pocket photographic specimen case, which has not been returned. Receiving no answer to the letters I sent for its return, I was induced to apply at the establishment where the advertisement came out, where they acquainted me with the address of the advertiser. I then made a personal application to him, when he informed me that the case had not been received, and that he was under the impression that his boy, in conveying it from that house to his own, must have lost it, which to my mind is not very clear, as the written application, which he admitted he received, was fixed securely to the case. Moreover, it seems very ungentlemanly on the part of an advertiser not to acknowledge the letters I addressed to him respecting it. I am not desirous of accusing anyone of wrong, but it does appear strange that after I left it at that establishment no clue can be given as to its whereabouts.—I am, sir, yours faithfully,  
SPECIMENS.

Oxford Street, November 2nd.

### COMBINATION PRINTING.

DEAR SIR,—I am not going to say that I have Mr. Tilley's secret, or that the method I am writing of has not been written about before, but if it has, I have not seen it, which must be my excuse for taking up your time. The method is this. Take any negative, block out the parts not wanted, then take a transparency of it; with that and a transparency of background, take a negative, and you have all that is wanted.—Yours respectfully,

A LITTLE GUN IN THE PROVINCES.

## Talk in the Studio.

NEW PAPER ILLUSTRATED BY PHOTOGRAPHY.—It is stated that an illustrated paper is to appear at Christmas the engravings in which will be executed by a new phototypic

process recently invented in France. The process is similar in its principal features to those already known. The pencil sketch is photographed, transferred to stone, then retransferred to zinc, which is etched by means of acid. Artists often complain that their pictures are spoilt by the engraver; it will be strange indeed if they do not complain as bitterly of the new phototype.—*English Mechanic*.

**SURVEYING BY PHOTOGRAPHY.**—The *South London Press* says:—"A South Londoner has invented a new scheme for photographing so as to give a comprehensive view of a large estate, or a pitched army, ground plans, broad acres, &c. This process is to take the picture by what is known as the 'instantaneous' process, the camera being projected, face downwards, from the car of a balloon. Of course this can be done only when there is a very trifling horizontal movement in the atmosphere, and when the aerial vehicle has been brought almost to a stand, by the sufficient liberation of gas when at a suitable distance from the earth. For mapping and surveying, the process promises to be invaluable."

## To Correspondents.

- H. C. COGSWELL.**—Pyrogallic acid may be kept for some time in concentrated alcoholic solution, a portion of which can be added to water for use. 2. Portrait negatives may be intensified by means of permanganate of potash. We have produced very good results with portrait negatives, simply immersing them in a solution of about ten grains per ounce.
- K. (Madras).**—The opaque spots or patches which appear on the negatives you describe is probably metallic silver, caused by contact with a dirty inner frame, or by the use of a horny, repellent collodion, or some one of a series of causes by which such a defect may arise; but with such slight data we cannot say with certainty which cause is in operation. But care in keeping the inner frames perfectly clean, letting the plates rest on clean blotting-paper, will aid you much. A bath in good order, and preciseness and cleanliness in manipulation, are, of course, important. 2. In such a country as you describe short exposure will, of course, be necessary. A weak developer, say five or eight grains of the iron salt to an ounce of water, and twenty grains of acetic acid.
- H. SPINK.**—The general plan of the studio appears to be pretty good. We fear that you cannot, with advantage, work two sets of sitters at once; there is scarcely space. The total length being twenty-seven feet, thirteen feet six inches would not be long enough for each; nor would the seven feet of top and side-light be sufficient.
- GLACIAL.**—The red untinted spots in albumenized prints are generally due to contact with something of a greasy or fatty nature—soiled fingers and similar causes. Possibly your albumenized paper has been fingered or lying about.
- GREAVES.**—You have been very successful. The retouching is well done, and you just stop at the judicious limits. The great danger in retouching is in going too far. Avoid that, and your work will gain. The example you send is very satisfactory.
- NORWICH.**—Dr. Mann, whose name you find in connection with the Photographic Society, is the same gentleman who spent several years in Natal and South Africa. His address is 5, Kingsdown Villas, Wandsworth Common.
- T. B. MELLOW.**—Your lighting is much improved. There is still, perhaps, just a trace more front light than is desirable; that is, the side-light extends a little too much in front. A more concentrated direct light would give you a little more relief and solidity, without destroying delicacy.
- R. F.**—Collodion for enamelling the surface of prints should be thick and somewhat tough. Several makers prepare a collodion expressly for the purpose.
- A. BEGINNER.**—The most useful work on colouring photographs which we can recommend is "Newman's Manual of Harmonious Colouring as Applied to Photographs," Newman, Soho Square.
- R. F. M.**—Platinum has been occasionally used for toning silver prints on albumenized paper; it gives a good black tone, but it is not, on the whole, better than gold, or even so good. The chloride of platinum is very deliquescent, and generally contains a large proportion of free hydrochloric acid, which causes it to bleach unless it be neutralized. It is a good plan to add carbonate of soda sufficient to give a slightly alkaline reaction, and then add a sufficient trace of nitric acid to make it neutral.
- H. W. B.**—No. 4 is most under-exposed, and Nos. 3 and 7 would have been improved by fuller exposure. No. 5 has been sufficiently exposed, but the subject is not well lighted, and hence a certain flatness. No. 6 is a difficult subject, especially with the special condition of light; but we do not think longer exposure was required.

**R. M. K.**—You may easily sell your chloride of silver to a refiner, if you have a sufficient quantity to make it worth the trouble. You can either obtain cash, or nitrate of silver to the same value. 2. It is not worth the trouble to attempt to save the gold from wastes in small quantities.

**M. P. S.**—The legitimate use of certain initials after the name, to indicate fellowship with a learned society—such as F.R.S. (Fellow of the Royal Society), F.S.A. (Fellow of the Royal Society of Antiquaries), F.C.S. (Fellow of the Chemical Society)—is confined to societies possessing a royal charter. A member of the Photographic Society using such initials would be committing a foolish error. Members of the Society of Arts have no claim to the use of the letters F.S.A. The desirability of securing to photographers the means of acquiring a diploma, or a legitimate claim of some kind to the designate initials, is a wide question, upon which much might be said for and against. At present no such facilities exist.

**D. F.**—Winter landscape photography is not generally very satisfactory or pleasing, except where special effects of snow or hoar frost, &c., are secured.

**COMMERCIAL TYRO.**—We cannot with propriety recommend special artists.

**MOULDY MOUNTING SOLUTION.**—Your solution of gelatine and gum may be preserved from mouldiness by the addition of an essential oil—or, better still, by the addition of carbolic acid. A trace of carbolic acid prevents decomposition in albumen, gelatine, glue, and similar substances, and will also effectually preserve from any tendency to fermentation paste of wheat flour or starch; and it effects this without in any way altering the qualities of the material, or, like corrosive sublimate and similar agents formerly used for preserving paste, introducing anything injurious to the photograph. If a few drops of tea-grain solution of carbolic acid be added to paste or glue when prepared for use, no fear of change or putrefaction need be entertained, as it at once destroys the germs upon which fermentation and decomposition depend. If glue be used it should be tested at the outset for acidity, and a little ammonia added if any trace of acid be present. Most samples of glue and gelatine in the market are more or less acid; the only article of the kind which we have reason to believe to be free from acid is a fine sample of glue prepared by a special process by Bevingtons, of Bermondsey. Where it can be purchased retail we do not know. Acid mounting material is most dangerous to photographs.

**ANXIOUS.**—There is considerable difficulty in photographing a vase or vessel of any kind of polished silver. One plan which has been recommended, and removes many difficulties, consists in placing some ice or cold water in the vessel, and photographing it in a warm room; the cold inside makes the vessel condense vapour on its surface, and so lose its excessive brightness, and become easy to photograph. But then there is the disadvantage that the true surface texture is not rendered. Try placing it in a curved background of black velvet, which will protect it from a multitude of reflections, use a concentrated light, and give a moderately full exposure. After one or two trials, you will doubtless hit the best conditions.

**MINIATURE ARTIST.**—We cannot explain the admission of some examples of coloured work and the rejection of others, except by suggesting that those admitted were illustrative rather of the application of a photographic process than as examples of colouring. If you require fuller explanation you had better write to the Secretary. We cannot tell you anything as to the future distribution of prizes beyond stating that no decision affecting the future has been formed. The only decision was that it would not be desirable to give prizes this year.

**A. YOKEL.**—We do not remember where or when Mr. Hughes published an unfavourable report on intensifying with permanganate of potash. We remember his observations on the defects of Selles's process, using ferrideyanide of potassium and persulphate of uranium; but nothing as to permanganate. The latter has doubtless escaped our observation. The results in our hands have been satisfactory. A rich brown deposit is obtained, of very non-actinic quality. We regard all such methods, however, as useful only in exceptional cases. As a rule, sufficient intensity can be obtained with the iron developer.

**N.**—The stains on the print are due to what are called "tear-drops." The silver solution, instead of drying off the sensitized paper in an even wave, has collected in drops. The use of a somewhat weaker bath, partially blotting off the excess of solution, using the paper not quite so dry before sensitizing, or removing the tear-drops with blotting-paper the moment they begin to form, will prevent the stains.

**A. G. GRANT.**—Should the Exchange Club be re-established, you will doubtless be able to effect exchanges of the kind you wish.

**HONESTE AUDAX.**—We will see that the needful steps are taken in Captain Abney's absence.

(Several Correspondents in our next.)

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### ROPY BEARDS—RECENT RESEARCHES UPON THE BROMIDE AND IODIDE OF SILVER—DETECTION BY PHOTOGRAPHY.

*Ropy Beards.*—Some remarks which have recently been made upon the blurred and ropy character of beards when reproduced by photography has led us to give some attention to the question. It is generally in the enlarging process that the abnormal state of the beard becomes most evident, as those who have essayed the production of large portraits of bearded models can testify. In the first place, our readers may not know that a hair from the beard is generally about three times as thick as that from the top of the head. In three pairs of specimens, plucked from the heads and beards of different patients, we found this to be the case, an object glass of quarter-inch focus clearly demonstrating the fact. Moreover, we found that with a moderate amount of light reflected upwards in the microscope all three samples of beard hair proved more or less transparent; while of those from the head, two were transparent and one—from a curly, black-haired patient—was opaque. The beard hair from the latter individual was, we repeat, in some degree transparent, and acted, like the other transparent ones, as a condenser of light when a beam of strong light was reflected upon it. It is a difficult matter to focus a hair sharply under the microscope, by reason of this ray of condensed light that runs the length of it; in fact, owing to its thickness, it never is all of it in absolute focus, and the blurring and widening of the object that takes place if the instrument is not properly focussed is known to all who have ever seen these capillary tubes under the microscope. The very coarse nature of the beard, then, compared with the hair on one's head at once hints at a reason why a large portion is rendered ropy; for any strong light falling on it is sure to be condensed in the same way precisely as if it fell upon a number of lenses, and these cause over-exposure—or what photographers call solarization—and blurring of the parts; and a little blurring or unsharpness in focussing in the original is, of course, much exaggerated in an enlargement. Pretty well the same thing happens in preparing carbon enlargements when one is not altogether *au fait* at the work. If a transparency formed of pigmented gelatine upon glass is put up against the light to be enlarged, it will be found that many of the lines and points are rendered on the focussing glass by broad streaks of light—the lines of a cottage roof, for example, appearing covered with snow. The effect is owing simply to the deposit of thicknesses of gelatine in these parts acting like a lens, and condensing the light, so that scarcely a sharp line can be obtained anywhere. Like the thick hair in a sitter's beard, certain lines in the picture are rendered coarse and solarised. In the production of carbon enlargements the difficulty is easily overcome by screening the transparency from direct light, and breaking it up and diffusing it by means of a ground glass diaphragm or other simple method. But to photograph a beard without its being rendered thick and ropy in parts is a problem not so easy of solution.

*Recent Researches upon the Bromide and Iodide of Silver.*—An interesting research upon the chloride and bromide of silver has been reported to the Royal Academy of Belgium by M. J. S. Stas, which includes several matters of importance to photographers. The details of his experiments with the chloride are published in the *Annales de Chimie*, and those on the bromide will follow in the next number. We will on an early occasion place before our readers such portions of the research as relate to photographic matter, and we have reason to believe that the remarks relating to bromide of silver will be especially interesting. M. Stas has carefully considered the changes brought about by

heat in the solubility of chloride of silver, and especially the influence of alkaline nitrates upon it. He has also given information upon methods of dissolving the chloride by means of nitrate of mercury, acetate of mercury, the alkaline acetates, and in a mixture of mercuric and sodic acetate.

*Detection by Photography.*—To use photography as a detective is not a new application of the art, and it is surprising what aid it may afford in recording facts which are not otherwise manifest to the eye. We do not here allude to the great spectroscopic discoveries that have been made from time to time with the assistance of the camera and sensitive plate, where lines have been recorded in photographic impressions of which no vestige could be seen by observers employing but ordinary means of vision. These discoveries have been made for the most part in the violet and ultra-violet portions of the spectrum, and since Dr. Vogel's discovery that by tinting a bromide film it may be made permanently sensitive to any section pretty well of the spectrum, we may hope to find out still more by photography by examining successively all portions of the solar spectrum in the same way as Draper, Rutherford, and others have investigated and added to our knowledge of the most refrangible portion. But it is not in its scientific bearing that we just now referred to photography as a detective, but rather as an aid in ordinary every-day life. Some time ago M. Gobert, who has charge of the photographic establishment attached to the Bank of France, communicated the fact that photography often assisted him in reading erasures upon cheques. If, for instance, one number had been scratched out and another written over it, the sensitive plate would tell him the word or figure that had been erased; for what appeared sufficiently removed to escape the eye usually proved quite clear enough to give an image in the camera. The photographer may become, therefore, an important witness in this sense, for any erasure or abrasion of the smooth surface of the sheet of paper upon which a document has been written, however neatly the scratching out may be managed, will produce a result upon the plate that cannot be gainsayed. A simple experiment will prove how sharp is the eye of the camera. Take a *carte-de-visite* that has fallen out of a letter, and which bears faint traces of writing upon its surface resulting from contact with the inside of the note; it bears, perhaps, but the faintest of marks, so that the picture may be placed in an album without reserve. But put it upon a screen and copy it, and the writing which is altogether illegible upon the original may be easily read upon the plate. A good deal has been done by paper makers to prevent cheques being copied by photographers, and all sorts of colours and water-marks are used; but we should not be surprised if one of the best safeguards against reproduction by photography would be the disposal of the fibre or glaze of the paper in different ways over the surface of the cheque, so that a photograph of the same would surely show patches just the same as if there had been erasures in certain plates, and the surface of the paper roughened in parts. Partial hot-pressing with metallic plates would, perhaps answer the purpose; to the naked eye the cheque would appear white and smooth throughout, and it would be only on copying in the camera that the surface-markings would become apparent.

#### FRENCH CORRESPONDENCE.

LEON VIDAL'S POLYCHROMIC PROCESS—DUCOS DU HAURON'S EXPERIMENTS—THE REFLECTOSCOPE PHOTOGRAPHIQUE—ENLARGEMENTS FROM OPAQUE PICTURES.

The first meeting of the Photographic Society of France, held this season on the 6th inst., will certainly be marked in the annals of the Society as one of the most interesting and numerous of its gatherings.

In the first place, I have to note the presentation, in the

name of M. Leon Vidal, of a large collection of new specimens by his process of photographic polyehromy. These were the feature of the evening, and I do not hesitate to say that they created as much surprise as admiration. It required one to have a large amount of confidence in M. Leon Vidal to be assured that the charming little paintings he has produced were not the result of artistic painting with a brush.

As he tells us in the note which accompanies his specimens, M. Leon Vidal has been engaged in perfecting his process ever since the moment he published it. He has applied himself to the simplification of the operations so as to render the method applicable to industrial purposes, and to allow of the pictures being produced at a moderate cost, so that the price might not exceed by more than a third the publishing cost of ordinary photographs produced by the usual methods of printing. His researches were especially devoted to the question of the relative value of photographic clichés, and to the modification of the negatives without the aid of a brush or a screen of ground glass. He models by means of photography those tints which he desires to bring back to their relative value in the same way as the light modelled the original cliché. It is well known that negatives such as are usually obtained do not reproduce nature truthfully in all its tints, the colours not being rendered according to their relative value. Green, yellow, red, and brown act upon iodide or bromide of silver with less intensity than the violet, the blue, and the white rays. M. Vidal has essayed to modify the clichés so as to produce them in the same condition as if the less refrangible colours had acted with the same relative power as violet, blue, and white.

In the pictures which he has sent to the Photographic Society, M. Vidal has attempted to reproduce objects of various kinds. Thus his collection contains several portraits, a bouquet of flowers, a flower by itself, a porcelain lamp (bronze and glass), ladies' handkerchiefs of various colours, a steam-engine, &c. Now as in the various pictures all the tints are reproduced from the most intense to the most delicate, every object is rendered with its colours finely modelled. Gold, bronze, brass, and iron have each of them their characteristic colours. In the steam-engine there are four different metals represented, each perfectly distinct from the other. Thus it will be seen that the process of polyehromy may be applied in every way to the reproduction of all sorts of works of art and industry. A cursory glance at the portraits and flowers will demonstrate numberless details, and show how precisely the author must have reproduced the different monochromes; in the bouquet, for instance, there are countless sprigs of all kinds, and yet the juxtaposition of the colours is as exact as the clearness of the lines are perfect. All the pictures, M. Vidal tells us, were obtained by the most simple means, and in such a practical and rapid manner that the number of copies is simply controlled by the number of monochromes that the clichés can severally yield. With the Woodbury press, or that of the Obernetter, or any other mechanical method, the yield of prints would be considerably augmented.

One important circumstance may be chronicled, viz., that with six or seven successive impressions M. Vidal is able to obtain much more complete results than those produced by means of chromo-lithography with twenty or twenty-five prints.

It need scarcely be said that there are no colours that are ill adapted to reproduction by this process: the most varied tints may be copied, and exact facsimiles thus secured. Neither do the dimensions limit one in any way, for enlarged portraits—as also the tiniest images—may be obtained by its means. We repeat that these paintings traced by light have been unanimously admired; and, on comparing the present examples with the earlier productions, we can only ask how it is possible that so much progress could have been made in so short a time.

At the close of the meeting the question was asked us, if M. Vidal would consent to receive pupils? "He will do more," was our reply, "for he is now preparing a manual, illustrated by numberless specimens, and which will contain such precise details that a perusal of it will permit of others doing the work as perfectly as he does it himself."

On his side, M. Ducos du Hauron presented, through his correspondent at Paris, M. Andoin, a specimen, of which I spoke in my last letter; at the same time he forwarded another memoir on the subject, of which I recently gave the chief points. It was possible to see, therefore, how far he, too, had progressed in polyehromy. But most attractive of all were the experiments of Mr. Geymet, of which I have also spoken, and which confirm, in the most positive manner, the theory of M. Ducos du Hauron.

After several other communications of less interest, and to which I shall possibly return, M. Van Tenac presented to the Society his *Reflectoscope Photographique*, the use of which he demonstrated before the members. The object of the instrument is to give enlargements of opaque objects just as well as transparent ones. One of the main points in the apparatus is the employment of an artificial light of some kind for supplying the illumination for the enlarging lens in such a way that all the rays of light are utilised. The image in this way acquires the maximum of illumination which the source of light can afford, the clearness being still further augmented by the use of a diaphragm in the lens. The power of the apparatus is such that, under ordinary circumstances, it is possible in a few seconds to secure an enlargement life-size from a carte portrait with a magnesium lamp of one ribbon. Even an oil lamp may be employed for the purpose, and this will furnish likewise very good clichés.

The apparatus, which is of but small dimensions, may be placed upon an ordinary table. It is composed of three distinct parts: the first is for condensing the light, as I said in a former letter on the subject, having in the interior a mirror of silver or speculum metal, which possesses a particular curve, and in the focus of this is placed the lamp. The second portion is for the projection of opaque objects, and is formed of a cylinder or trunk-like cone, placed at 45° at a certain distance from the condenser. In this is fitted a door where the object to be enlarged is placed; perpendicularly and *vis-a-vis* to the centre of the door is fixed the tube with the lens. The third portion is for the enlargement of transparent clichés; it is formed of a cylinder or trunk-like cone, or of an ordinary camera fitted on one side with a frame for placing the clichés, with a lens on the opposite one, having its axis coincident with that of the condenser. A chimney where the supply of air is provided, a tube for conducting the smoke out of the apparatus, and a case in which it is fitted, completes the whole affair.

To obtain an enlarged photographic impression of an opaque carte-de-visite, or of a transparent cliché, the manipulation of the apparatus is very simple. After having fixed the object to be enlarged in its proper place, the top portion of the apparatus is turned in such a way that the enlarged image is projected on to the screen; the screen and the object are then in the same parallel, and the lamp is introduced into the instrument, and the image is focussed, the dimensions being controlled by moving the screen to and fro, and adjusting the lens. After having prepared the sensitized plate, or sheet of paper, this is put into its place upon the screen. The magnesium is then set fire to, the other lamp which has served for focussing having been withdrawn. The period of exposure varies according to the importance of the enlargement, and according to whether the object is opaque or the transparency clear or dull; it varies, also, with the quality of the lens and with the diameter of the diaphragm employed.

M. Hermann, who daily employs this apparatus, made the

following remarks upon its merits:—"This new instrument is an improvement upon the different enlarging instruments used up to the present day. The possibility of obtaining direct an enlargement from a carte-de-visite, without, in the first place, having to secure a small negative, is a most important matter, for almost always a great deal of half-tone is lost in the ordinary process of copying; moreover, the light and shadows become exaggerated, and the likeness, in this way, is often lost. It is only necessary to glance at the direct enlargement of a carte-de-visite upon the screen of the *reflectoscope* to be convinced of the fineness and delicacy that are obtainable. Another important point is, that one is not dependant on daylight for carrying on one's work."

The employment of magnesium has never been employed in such a practical manner as in the present apparatus, by reason of the difficulty of getting rid of the dense fumes which obscure the condenser after the lapse of a few moments. This difficulty has been altogether overcome by an exit established above the apparatus, while drafts properly conducted suffice to remove the smoke entirely from the chamber, and allow the magnesium wire to burn regularly.

The extreme rapidity of the operations upon collodion render it unnecessary to pay any attention to the cost of the illumination. With a very transparent positive, a few seconds only are necessary to obtain a head of life-size. The whole of the light is then made use of, and clichés are secured of the clearest and densest character.

The experiments made at the meeting by M. Van Tenac were completely successful, and quite confirmed the flattering remarks made upon the occasion by MM. Hermann et Andra, both of whom spoke enthusiastically in praise of the new instrument.

ERNEST LACAN.

## Correspondence.

### IMPROVED TRIPOD STAND.

DEAR SIR,—I hoped that I might render some slight service to my kind photographic friends, and my brethren generally, when I wrote the letter which appeared in your issue of the 18th September last, as regards my "legs".

Imagine my disappointment (not to use a stronger term) when I find in your paper, received on Saturday last, that a Mr. Oakley has exhibited at the South London meeting a tripod, with some talk of "copyright" on the part of Mr. Tully, which as nearly as possible corresponds with mine, which (mine) have been in use for the last two years, as everybody knows who is connected with me. Every one of the photographs exhibited by me in the Suffolk Street Exhibition just closed was taken on the top of that stand, besides scores of others, though it has been altered slightly and improved since my return to England.

I heard from London a fortnight since that some one was making legs like mine, and saying they were his invention, but I did not hear any name. My desire was, if any benefit could be derived from my ideas, that all should be benefited. I took my original tripod to Mr. Morley, of Islington, to improve for me, and to be a guide for the taller set which I named in my former letter to you on this subject; and the description read by the Secretary before the South London Society is so extremely like a description of my own legs, that I cannot help thinking some one must have borrowed an idea.

How I came to invent the tripod is as follows. My instructor in photography, Signor Guidi, of Sanremo, had two sets of tripods of French make, which have two screws to raise or lower each leg and fix them; and the inconvenience of the complication at once struck me.

I bought a set of the ordinary doubling up legs, and a carpenter (by name Asquasciati) at Sanremo, by conversion, made me those which I have ever since used, which have only one screw.

The slippery pavements, the top of Milan Cathedral, and many other difficult positions, disgusted me with the ordinary triangle top, and I adopted the French arrangement, with screws at the heads of the legs, rendering them non-collapsing.

Far be it from me to claim anything to which I am not entitled, though the adaptation may be my own. When I was in Venice I met Mr. Norman, one of Mr. Frith's operators. From him I got the idea of raising the camera so as to be out of the reach of the peering people, &c. He had a heavy ordinary (not doubling up) tripod, and had ingeniously joined to it an additional joint to each leg hinged at the bottom, so that he could let it down or put it up as he found convenient; but it was, I thought, *very heavy*. I saw no difficulty in lengthening my tripod, according to my own plan, so as to answer the same purpose, perhaps even more conveniently, and this, I believe, has proved the case.

There is another point on which I must trouble you, viz., "the ball and socket joint" of Mr. Oakley and others. I think that action is not adapted for taking panoramic views or moving objects with the greatest facility. If the arrangement on the top of my legs be properly constructed, the camera can be turned completely round "without the possibility of any change of plane," and no re-leveling or re-focussing is requisite. It is not a ball and socket, but a levelled block turning in a socket.

I send you my original legs as improved, so that you may judge for yourself. If you look up by the side of the spike when closed up you will see a small brass female screw let into the leg, through which the fixing screw works. This, though a trifle, is important, because without it I found the wood soon worn away with constant use.

As Mr. Morley has asked the loan of my tripod in order that he may take patterns of the brass work, I shall write to him to say that I have sent it to you, and that he can send for it when you have done with it.—I am, dear sir, yours faithfully,

T. G. A. PARKYNS.

Catherston Manor, near Charmouth, Dorset.

[The legs forwarded to us by Sir Thomas Parkyns undoubtedly possess the convenient extending arrangement which was the especial advantage in those described at the South London meeting; the chief difference being that our correspondent's admit of more extension.—Ed.]

### TRADE PUFFS IN THE SOCIETY.

SIR,—Will you allow me, as a very old member of the Photographic Society, to protest against the growing tendency, which is manifest, to use the papers read before the members as vehicles for advertising the wares of various manufacturers: the use of Mr. So-and-So's collodion, the lenses of Mr. Some-one-else, and the camera and various other articles by Messrs. *Les Autres*. At one time a distinct understanding existed that all such allusions should be eliminated from papers, either by the council or its secretary, and our presidents of old were prompt to suppress undue shoppiness in the discussions. *Mais nous avons change tout cela*, and there is some danger of the Society losing its scientific interest altogether, and degenerating into a trade organization; and its meetings into occasions for the feeblest possible talk on the most trivial possible points belonging to the duties of an operator's assistant—a kind of thing which on Tuesday night I regretted much to see approved, and as much as possible prolonged by the chairman. Surely we might expect from the president, who, it was anticipated, would look so well after science in the society, something better than this.—Yours truly,

N. L.

[The tendency to trade allusion, of which our correspondent complains undoubtedly seemed manifest on Tuesday evening. Some degree of inexperience in various quarters may possibly explain the circumstance. When the Society and officers get fairly settled to their work after late disorganization, all this will doubtless be put right.—Ed.]

## COLLODIO-BROMIDE EMULSION.

SIR,—All photographers who practise dry-plate processes must feel indebted to Mr. Phipps for his generous publication of what appears to be an admirable mode of preparing collodio-bromide. Nothing can be simpler than preparing plates with such an emulsion.

In the hope that a further improvement—an economical one—may be made in compounding the emulsion, I venture to suggest that the plan of evaporating the solvents to obtain the film in a state fit for washing appears to be somewhat wasteful. Is it not possible to prepare the bromide of silver washed with water and subsequently with alcohol, to free it from the soluble salts, and then form an emulsion by adding it to the collodion? The mixture being mechanical, the complete suspension of the particles of bromide of silver may possibly be accomplished without the waste I have referred to.

R. T. J.

[The addition of bromide of silver, prepared before-hand, to the collodion has been practised; but there is some difficulty in preparing in this way an emulsion without tendency to subsidence. We shall be glad to publish the experiences of any experimentalist.—Ed.]

## WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

SIR,—The preliminary meeting for giving the above Society a veritable existence will take place on Monday, the 16th inst., at 7 p.m., at "New Inn," opposite Town Hall, Bradford.

I had to settle upon some central position in Bradford, and the above was thought the most convenient as an initiatory step until private rooms could be obtained.

This explanation is perhaps necessary to the Good Templars who may be found amongst the intended members.—Very truly yours,

J. W. GOUAN.

*Akroydon, November 10th.*

## PHOTOGRAPHIC IRRADIATION.

CONTINUING the discussion on this subject, Mr. John Aitken wrote, some time ago, in *Nature* :—

"I hope you will allow me space to correct a slight misunderstanding which has got into the present discussion on photographic irradiation. Mr. Crofts places my views in opposition to those of Lord Lindsay and Mr. Ranyard. Mr. Stillman, who has given us such valuable information on the molecular condition of different preparations of collodion, also takes the same view. Now, in reality, Lord Lindsay's and Mr. Ranyard's views are not opposed to mine. I have simply attempted to prove that molecular reflection was a cause of photographic irradiation, not that it was the only cause, as I quite agree with Lord Lindsay and Mr. Ranyard, that the imperfections of the lens are also causes of photographic irradiation, and in *Nature*, vol. x. p. 185, I pointed out one form of irradiation due to the lens. But the imperfection of the lens which is most fatal is that pointed out by Lord Lindsay and Mr. Ranyard, namely, the inability of the lens to bring all the rays to a focus, whether this results from the imperfections of the outside portion of the lens, or from imperfect achromatic\* correction. No maker of lenses will tell you that any lens, far less that every lens which he puts out, is perfectly corrected for dispersion. Working with such an instrument, it is very clear that if we only allow an exposure sufficient to give an image on the part of the collodion where the great proportion of the rays are focussed, then the photographic impression will give very nearly the true boundary line. But suppose we allow more light to pass

through the lens, either by turning the camera to a brighter light or by giving a longer exposure, then it is clear that the unfocussed rays, which gave no impression when the exposure was short, will now impress themselves on the collodion, and thus the photographic impression will be extended beyond the true boundary line. That there should be difference of results in experiments on photographic irradiation is quite to be expected, as there are so many variables in the experiments. The light, temperature, and condition of the collodion are all constantly changing, and the conditions under which the experimenters work, and the apparatus and chemicals used, are different for each experimenter; different results may therefore be expected. If the experimenter use a good lens, and employ only the central portion of it, the imperfection due to the lens may be small in quantity; but if his lens is imperfectly shaped and badly corrected for dispersion, and he uses the full aperture, the result will be very different. Again, if the experimenter work with different collodions, Mr. Stillman has shown that, altogether independent of the lens, a very slight change in the preparation of the collodion greatly alters the amount of irradiation. So far as I can at present judge, the imperfections of the lens and molecular reflection are not opponents, but allied enemies, which we must meet on the same field."

Writing to the same paper, a week or so since, from Florence, Mr. A. Cowper Ranyard makes the following reply to the above :—

"I shall be obliged if you will allow me space to state more specifically why I am not able to concur in the irradiation theory of Mr. Aitken (vol. x. p. 439). I understand from his last letter that he fully agrees with Lord Lindsay and myself as to the cause of the outer irradiation, and our only difference of opinion now lies in the amount of the inner irradiation that can be traced as due to what he has termed molecular reflection within the thickness of the collodion film. Mr. Aitken and Capt. Abney both appear to consider this as the chief cause of the inner irradiation fringe, while I am disposed to rank the irradiation arising from the optical imperfections of the instrument with which the photograph is taken, together with any irradiation that may arise in the wet plate processes from circulation in the film of fluid covering the plate, before, or as very much greater in amount than the irradiation due to dispersion within the collodion film.

"We should expect that light dispersed within the thickness of the collodion film would produce its photographic effect in all directions round the illuminated point, and that the area of action would not be affected—or certainly would not be decreased—by covering the front surface of the portions of the collodion film adjacent to the directly illuminated area with an opaque object. Indeed, if the opaque object were a good reflector—such as a bright piece of platinum foil—we might expect slightly to increase the area of photographic action due to dispersion within the film; for the light dispersed towards the front surface of the film would be in great measure reflected back into the thickness of the collodion. But, as I have shown in former letters, placing a piece of platinum foil in immediate contact with the collodion film causes the photographic image of a bright image to be sharply cut off, and no perceptible irradiation can be traced under the edge of the foil.

"Again, we should expect the action of dispersed light to extend further within a thick film of collodion than within a thin film; for there would be a greater thickness of illuminated collodion, and the angle through which light could be radiated directly upon the adjacent area without suffering reflection at either surface would be increased, but I have not been able to detect any perceptible difference in the amount of irradiation of similarly exposed plates coated with four thicknesses of collodion and in those coated with but one film.

"I have felt myself, therefore, driven to look for the cause of irradiation either in some circulation taking place within the film of liquid covering the collodion at the time of exposure, which film would be interrupted and its tension greatly altered by the contact of a solid body; or else to seek its explanation in the optical imperfections of the photographic instrument. Possibly, in the wet plate processes, circulation within the fluid film may produce a very sensible effect. Indeed, there are phenomena which make this more than probable. When a wet plate picture of a strong light projected upon a dark background is taken with a decided over-exposure of say ten minutes or a quarter of an hour, the inner irradiation fringe is seen to

\* We here require some new word, or we must greatly extend our conception of achromatism, as we have here to deal with rays far beyond the limits of the sensitiveness of the eye; and the word achromatic, as applied to lenses for chemical purposes, is somewhat misleading. I may here offer two suggestions as to how the imperfect power of the lens to bring all the different rays to a focus may be partially corrected:—(1) By using a collodion which is as nearly as possible only sensitive to those rays which the lens can bring to a focus; or (2) by providing each lens used for making accurate observations with a screen, which shall stop back all the rays beyond the limits which the lens can focus.

be most opaque on its outer edge; and the phenomenon is so marked that it cannot be held to be an effect of contrast. This, of course, should not be the case if the irradiation edge were due merely to the optical imperfections of the instrument. Again, in the small negatives of the eclipse of December, 1871, taken at Dodabetta and Baikul, there is a decided structure in the irradiation under the prominences: under the brightest of them it can be distinctly seen that the opacity of the irradiation fringe is greatest along lines radiating from the prominences; while along the outside—that is, furthest from the prominences—there is an arc of slightly greater intensity. The same structure is traceable in all the negatives, but it is most marked in the Baikul series, and especially in those negatives in which the prominences are most exposed, viz., on the east and west limbs, at the beginning and at the end of totality. This, of course, cannot be accounted for merely by the optical imperfection theory. Again, the little brushes mentioned in a former letter as extending under the edge of the platinum foil cannot be accounted for without supposing that there is circulation within the liquid film. I hope on my return to England to carry out some further experiments for determining the amount of the inner irradiation which in the wet-plate processes may be due to such circulation."

### THE PRACTICAL PRINTER IN AMERICA. XIII.

*Filling of the Frames.*—The simple process of filling the frames, as far as *teaching* it is concerned, is often very much neglected by the photographer in learning his apprentice to print.

This neglect on the part of his teacher of photography instils into the mind of the inexperienced printer a disregard of the importance of this mechanical operation, and thus quite often blunders, mistakes, and breakages of negatives occur, which is called *foolishness, heedlessness, &c.*, by the photographer, and his apprentice is quite often *cursed* by him for his stupidity. The apprentice is of course somewhat to blame, but the photographer, unless he has fully shown the danger which would arise from not being careful in filling, is *equally* to blame, at least for the first or second accident.

When a young man first commences to print, he should *then* be taught the carefulness required in filling the frames, and in hopes that this chapter may arrest the eye of the young beginner, I have attempted to show in what respects carefulness is required.

I have said that this carefulness should be instilled into the mind of the young beginner when he *first* commences to print. There is an old saying, "It is hard to learn an old dog new tricks" and although your printer may not be an *old dog*, yet it is applied to beings possessing more intelligence equally as well.

When a printer has learned to print carelessly, then it is very hard to learn him carefulness, and consequently such a printer will always be making mistakes all his life, however experienced at printing he may be. Such is partly the reason why every person who contemplates learning the photographic art should learn in a gallery where good work is done, for in learning how to make good work, *carefulness* is also learned, which is always a necessary accompaniment. Now, the placing of the negative in or on the printing-frames is not altogether the *simplest* thing in the world, and in placing it in to print, please remember that glass is quite brittle, and that it does not take much to break it, and very often in letting the glass fall in the frames, after having placed one end in, causes it to break, on account of some slight flaw along the edges.

For this reason the negatives, before they are even retouched, should have the edges cut *clean*, providing they are not already so, as then there will not be so much danger of their cracking from uneven cutting.

The negative, if it be a trifle large, should *never* be forced into the frames to save a little trouble in cutting it, for they can never be forced into place, and either the frame or the negative will have to give way to the pressure, and

the negative will most likely be the one. If the negative is a little short or narrow, or both, then a clean glass of the same size as the bed of the printing-frame should be placed in it, and the negative on top of it. Then if anything give way, it will be the plain glass. It is always better in printing from negatives as large as 8 by 10, or larger, to have an extra glass in the frame.

The dusting of the negative, to remove any dust that may have settled on it, should be accomplished by a wide, soft blender of camel's hair. To dust the negative, *never* lay the flat side of the brush *horizontally* to the negative, and then draw it along, for a great proportion of the dust will stick to the negative; but the brush should be held *perpendicular* to it, and the tips of the hair used briskly.

Dust the negative two or three times, and immediately after dusting place your paper on it before the dust settles again.

In placing the paper on, many printers spoil their prints by not placing it up high enough on the negative, and then again by placing it too high.

Paper with metal and albumen spots on it can be very often saved, when the albumen spots are not too large, by placing that part of the paper containing the spots on the deepest shadow parts of the negatives.

In placing paper on vignette negatives, choose the very best, and never place paper on them that has the *water-mark* on it.

In printing such paper on any other negative, always have the water-mark on the darkest side of the background. As a rule, always place the imperfections of the paper—when you think that it can be saved—on the negative so that they will come in *all cases* either in the hair, draperies if dark, or in the shadow parts of the negative.

After placing the paper on the negatives, a cloth or two should be placed in. The reason why the cloths should be placed next to the paper is because better contact is secured thereby between the negative and paper. These cloths or pads should consist of white cotton flannel, *unmapped* side out—i. e., next to the paper—as the other side often causes imperfect contact between the negative and paper.

They are sometimes glued to the back of the board (i. e., the backboards), and then they do not need more than a single pad in the frame. When there is another glass in the frame, do not use more than *one* pad, as the pressure of the backboard will be too strong for safety to the glass. Instead of cloth pads, thick blotting-paper may be placed next to the sensitive paper, and the cloths next to them.

There has, within two or three years, a novelty appeared of fuming these pads very strongly, and placing them on the negatives, and thus fume the paper while printing. It is said by some to be very beneficial to the paper.

When fuming-pads are to be used, they should be fumed all night in a perfectly air-tight fuming box, and then after they are used once, they should be placed back again and kept there while the fresh pads, which are removed from the box, are used. On placing the pads on the paper, look to see whether there is any dirt on them, and whether there is anything on them that will spoil the paper.

If there are any tacks on the bench where the pads are laid down they are apt to stick to the cloth, and if they are not examined closely, and shaken before they are placed on the back of the paper, they will eventually break the negatives. In laying the backboards with cloths glued to them down on the bench, *never* lay the cloth side *down*, but always *up*.

After printing the first print, look closely at it, to see whether there is perfect contact in all parts of it.

In adjusting the pressure, always have it as *gentle* and *even* as possible, as strong and uneven pressure endangers the negative. Clean the back of the negative with a woollen rag, wet with a little common alcohol, before placing it out to print.

## PROPERTY IN PORTRAIT NEGATIVES.

THE question, To whom does a portrait negative belong? is again brought before the public by the press, and in a manner which illustrates the shallow and nebulous notions which prevail on such subjects, even amongst those who undertake to decide upon them *ex cathedra*. A distinguished artist and photographer, who is beloved and esteemed throughout the profession, has recently, we regret to say, through a serious break-down in his health, been compelled to relinquish the active pursuit of his profession. Having a large stock of portrait negatives, the majority of them as valuable as works of art as they are as portraits, he resolved to afford the families of the original sitters an opportunity of acquiring the negatives, rather than permit them, in the possible sale of his effects, to pass into hands beyond his control. To this end he issued a circular addressed to his customers, offering the negatives for which they had sat, on special terms. This circular, possessing rather the character of a private letter than a public document, we should not have felt it right to publish here, had it not already been printed, with misappreciative comment, in an evening journal. We reproduce it for the purpose of explanation, and comment on the general question. The circular runs as follows:—

London, Sept, 1874.

Mr. R—— presents his compliments to Miss ——, and begs to intimate that, owing to the accumulation of portrait negatives in his studio, he is compelled to dispose of them, and is induced to offer for sale the negatives of the members of your family from whom he has had the honour of sittings. Mr. R—— feels that in all cases when an artist allows a portrait negative to pass out of his hands, the sitter or the family become the proper custodian, in order to avoid such of the negatives passing into other hands, and so becoming lost sight of, or even misused. Negatives are unfading. He therefore now offers them at a very low price, in order that they may pass into proper hands. These negatives in most cases have given much satisfaction, and in many instances possess a pictorial interest independent of that belonging to the mere question of likeness. They can, of course, be printed from at any time, by any photographer, and they permit also of the production of enlarged or diminished copies, which may be finished by any artistic method. The negatives belonging to your family Mr. R—— offers at £1 1s. each, or £2 2s. for three plates; cards at 10s. 6d. each, or 21s. for three. An early answer will oblige, in view of other arrangements.—I remain, &c.

This circular, relating so essentially to a matter between the photographer and each customer to whom it was addressed, appears to an evening journalist fraught with some degree of public peril, as involving a "blackmailing element" which he should be "sorry to think was viewed with favour by photographers generally." As the real object of the circular was to offer a privilege, rather than to levy blackmail, and to provide an escape from the contingent evil of the negatives passing into irresponsible hands, the photographer wrote an explanatory letter to the journal in question, which it has not, so far as we are

aware, yet published. After explaining that he was suffering from a long lingering illness, he added:—"If I die this winter, my negatives and photographic stock-in-trade would be disposed of somehow beyond my control. Now I have given a chance to those who wish to preserve the negatives in their own safe keeping, to do so at a small price, for many of them are worth a good deal." He adds:—"There might be another contingency. Suppose I could not pay my rent, my landlord would come in and seize my stock, and the sale would then be very promiscuous." This explanation might possibly be quite sufficient to remove the misconception of the evening journalist; but a weekly satirical paper is more unreasonably severe, and, as a consequence, less likely to disquiet the public. He says:—

A well-known photographer is notifying his patrons by circular that, owing to the accumulation of negatives in his studio, he is obliged to dispose of them by sale; and in order to prevent them from coming into the hands of persons who might make an improper use of them—of course, *he* would not do such a thing—he offers them to those who sat for them at a stated price, which, by the way, is a rather high one. It does not seem to have occurred to this simple-minded creature that the danger from which he is so anxious to protect his customers might be more easily averted by merely destroying the negatives instead of selling them to their owners. Indeed, those unfortunates might be shielded with reasonable effectiveness by receiving back their property free of charge. Probably, however, the good man is about to go out of the business—after this he will find that course greatly to his advantage—and in the hurry of winding up his affairs has mislaid his honesty. It would ruin a thief to find it.

The offensive remarks as to mislaid honesty may be passed by in the assurance that it would not have been made with a fuller knowledge and understanding of the circumstances. The simple question to be decided is, whether a photographer is guilty of unfair practice in offering to sell his negatives to the original sitters to avert the probable contingency of their distribution by sale into various, and, possibly, unscrupulous hands. The provisions of the Copyright Act are very ambiguous in relation to the copyright in portraits commissioned in the ordinary practice of the profession. It is doubtful whether, according to the terms of the Act, any copyright accrues to any one in such portraits; but it is held by some who have carefully considered the question that the copyright becomes the property of the sitter. But in either case there can be no ground for pretending that the negative is the property of the sitter, any more than the lithographic stone upon which a design is printed by a lithographer to the order of a customer. The contract between the photographer and his sitter is in all cases for a certain number of portraits, and, these supplied and paid for, the contract is completed. The negative is an intermediate necessary aid in the producing the portraits: it belongs to the photographer, and, of course, remains in his hands. No respectable photographer, no matter what may be his estimate of the provisions of the copyright law, would dream of printing from such negatives to the order of any one but the original sitter or his legitimate representatives; but the possession and preservation of a stock of such negatives become a valuable property as securing a connection for further orders. Whilst the photographer continues in the business, himself the custodian of his negatives, no difficulty need arise; but if from any cause a transfer of his stock become necessary, possible troubles commence. In the voluntary sale of a stock of negatives most respectable photographers will have some regard to the probable trustworthiness of the purchaser who is to become custodian of the portrait negatives of his sitters; but he cannot have absolute certainty unless he made conditions which would hamper the sale, and which as a matter of fact no one ever dreams of making. In the case of death or seizure by a landlord, the sale would be, as the photographer above quoted remarks, of a "very promiscuous" character. It appears, then, that the only absolutely safe, fair, and unchallenge-

able method of disposing of negatives consists in offering them to the original sitters, who have a contingent interest in them. The suggestion that the photographer should hand over such negatives to his sitters, on the assumption that they are their property, is of course out of the question. The negatives are not the property of the sitter, who neither ordered nor paid for negatives any more than they paid for cameras. They ordered portraits, received them, and, we hope, paid for them; but, except to be assured that they are not misused to their disadvantage, have no rights of ownership in them. The other alternative which our weekly contemporary suggests—destroying them—is certainly within the power of the photographer; but besides the absurd improbability that he should destroy many hundreds of pounds worth of valuable property, he would be guilty, in many cases, of an act of vandalism which nothing could justify. In many cases, as in that immediately under attention, the negatives are very noble works of art, which it would be iconoclasm of the most deplorable kind to destroy them. In many cases they would be portraits of the beloved dead, and the loss would be beyond repair. In either case the sitters and their families have a strong interest in the preservation of such negatives, and there exists scarcely one of them, we will venture to assert, who does not regard the opportunity of securing the negative from destruction, or straying, a boon for which to be grateful, rather than as impost of black mail which they must pay to avoid a more objectionable annoyance.

A revision of the law of copyright could scarcely settle the proprietorship of the negative, as, unless its cession to the sitter were involved in the contract and recognised in the purchase money, the indisputable investiture of the copyright in the sitter would not necessarily carry with it the ownership of the negative; and if, by any rearrangement of the understood contract between the photographer and his sitter, the negative passed into the custody of the latter, he would find it a most troublesome charge, its final injury or destruction being, in nine cases out of ten, almost inevitable. Further, such an arrangement would, beyond a question, lead to an increase of cost or a falling off in quality. Most photographers of artistic ability spend more thought and care upon producing a portrait negative than are paid for in the immediate commission, because they regard that negative as involving reputation and future income. If it pass out of the first artist's hands to be printed in future by one beyond his control, his hope of future income is at an end, whilst, so far from gaining reputation, he may absolutely suffer loss if his name be associated with the negative, from the carelessness or incapacity of some incompetent printer, into whose hands his negative has been placed to produce cheap copies.

#### THE PRESS ESTIMATE OF THE EXHIBITION.

AMONGST photographers the estimate of the general excellence of an exhibition will vary very much, depending on the special subjects of interest in which each is concerned. With one, progress in the art would be illustrated by a good display of landscapes; whilst another would augur ill for the general advancement if the portraiture were poor or commonplace. The triumph of dry processes would represent the millennium of the art to some; whilst to others it would seem "in a parlous state" so long as the practice of permanent printing was the exception, and not the rule, amongst photographers. Whatever may be the special views of photographers themselves, they are generally interested in ascertaining what are the views of intelligent outsiders upon their annual exhibitions; and this they may, to some extent, ascertain from the criticisms of the press at large when they condescend to notice the display of photographs. Assuming that this work were always done by capable art critics, their deliverances should be very instructive, and photographers might at least defer

to their judgment as to how far artistic progress kept pace amongst the fraternity with the steps of technical improvement. Unfortunately, it happens that such authoritative value cannot be attached to these criticisms. The critics are apt to run in grooves, and to feel it safe to praise either acknowledged success, or that which certain schools consider success. The rule of criticism in such matters continues very much of the character which Goldsmith set down the Vicar of Wakefield, included in the simple formula, "Praise Pietro Perrugino, and say that the picture would have been better if the painter had taken more pains." But whilst some of the criticisms on the present exhibition are hasty, superficial, inappreciative, or even misappreciative, there is still often much to be learnt from them by the thoughtful photographer.

The fullest, and probably the best, daily press notice appeared in a journal from which least might have been expected, the *Morning Advertiser*, the organ of the Licensed Victuallers. It will be read with interest, but does not demand especial comment. The brief notice of the *Daily News* was little more than an indication of the existence of the exhibition. The *Observer* was more critical. Dealing with the larger pictures in the Crawshaw competition, the writer had some very just remarks on the painful character of a life-size literal transcript of the human face, which is nothing more than a transcript. "We cannot but feel," the writer says, "that the nearer is the approach made to imitative perfection, the more obvious and marked is the distinction between this art and that of painting in its nobler and more intellectual form. There is apt to be something almost painful in a large life-sized reproduction of human features; and we seem to lose the expression of a face, as we do that of a natural scene, while we are engaged in tracing the fidelity of transfer of every detail. The further we descend into particulars the more do we feel the want of that artistic spirit of order which marshals the facts of a subject, and so presents them to the mind of the spectator as to convey to him the same impression that the facts themselves have conveyed to the mind of the artist." All the force of these remarks is manifestly directed against such pictures in the form of untouched photography, without the softening, harmonizing touches of the artist, beyond a question necessary in photographs of this size. Referring to the resources available to the photographer for ameliorating photographic crudities, the writer commends Mrs. Cameron's alleged practice of placing the sitter out of focus so as to secure the general effect of light and shadow rather than a perfect rendering of a perfect texture of the skin. The device in question has its valuable uses, but is surely a fault rather than a virtue where it is applied to all faces, and so loses the delicate and sweet texture of the skin of the young beauty, as well as the rugose or wrinkled texture of skin to which time or nature has been less indulgent. For a judicious application of this device we might refer the reader to some of Mr. Blanchard's pictures. Where the skin is of fine texture it is finely rendered; but where, as in the portrait of an eminent tragedian, the face is deeply pitted with small pox, the merciless sunlight is not brought to focus on the skin: it is just sufficiently near focus to give the generalized suggestion of texture, without rendering every scar with minute literalness; but there is nothing smudgy or fuzzy in the general result, as there is in many of the pictures of the lady in question. The *Observer* thinks it fortunate that there are no more "composition pictures," which "are apt to be a weak kind of masquerading and sham sentiment, as in Mrs. Cameron's 'King Henry,' and the 'Children playing at saying prayers for their father at sea.'" It is a device as unfair as it is stale, to measure a thing by its failures. In the best examples of photographic composition the critic sees no suggestion of masquerading, and is apt to accept the result as a copy of a painting.

Mrs. Cameron exercises the critics considerably. The

*Standard* assigns her portraits the highest place, for the very odd reason that they most resemble something they are not. He does not judge them from an independent standpoint, and test them by the legitimate standard of their truth to nature, without violating the canons of art; but likes them because "they best realize the style of the best painters," and call to mind "pictures of the old schools." The excellences of the best painters, in so far as they consist of fine composition, arrangement, and light and shade, are qualities desirable in all forms of portraiture; but the realization of the special qualities of a master, such as roughness of handling, broad, sketehy, or suggestive treatment, rather than minute, perfectly made out work, is opposed to the whole genius of photography; and the imitation of the accidental qualities, such as the loss of detail and general deterioration through the destructive action of time, is surely a fault of a grave kind. The phrase used by the critic, we believe, precisely indicates the cause and character of the defect in Mrs. Cameron's work. She imitates the style of painters past and present, and the pictures of the old masters rather than nature; and, with much undeniable artistic quality, her pictures are too often far short of what, with a truer standard in her mind, she would make them. The critics, who have for a long time flattered Mrs. Cameron, often seeing artistic profundity where there was only confusion, have begun to tire of the slovenliness of execution, accidental or intentional. The *Times*, in speaking of the portrait (fine in many respects) of Miss Bateman, to which the line from Tennyson, "Urania speaks with darkened brow," is attached, says:—"The aptness of the quotation cannot be denied, for the brow of Urania is so remarkably dark that it is with difficulty we can separate it from the background of flowing hair and the overhanging boughs beneath which Urania stands. Distinctness is surely one of the first essentials in a photograph. In large breadths of landscape and composition pictures this is a quality undoubtedly difficult of attainment with the camera, but we confess we should not be inclined to allow this excuse to portraiture. The colour in which photography appeals to the eye is not in itself pleasing, though, of course, this is far less apparent in some instances than in others; but when to this unavoidable defect is added a slovenliness of execution (whether from accident or design), then, we submit, the photograph is lacking in one of the first requisites of good photography. There is apparently a growing tendency towards this style of work among amateurs, which we fail to notice among their professional brethren, and it is on this hint we venture to speak."

We scarcely think that there would be many followers of this style; but we have devoted more space than is, perhaps, necessary to point its error, because many of these pictures have received much indiscriminating praise on the ground that they resembled old masters, and this praise might tempt other students into the same path. The glory of photography is, that it can render with a truth, delicacy, and minuteness, details beyond the skill of the painter to realize; and to forego these special qualities, and emulate others in which it must at best produce second-rate imitations, is a folly which will not, we hope, find many disciples amongst earnest photographic students.

The *Times* critic is generally appreciative and just to the pictures in Suffolk Street, and the review which appeared in our last was doubtless read with interest.

#### MR. STILLMAN'S COLLODIO-BROMIDE POWDER.

REFERRING to the preparation of collodio-bromide of silver in a dry powder for keeping, analogous to Mr. Kennett's pellicle, we find in *Anthony's Bulletin* the following details:—

"Without recounting the different modes of working and compounding emulsions, we will content ourselves

with stating that Mr. Stillman, after making his emulsion, dries it, removes from it all free nitrate of silver and all other soluble substances which might act prejudicially to the keeping qualities of the plates, and then reduces the material to a powder. This is put up in light-tight bottles, and can be sent everywhere by mail. For use this powder must be dissolved at the rate of seventeen grains to an ounce, of a proper mixture of ether and alcohol. Albumenized glass, being already prepared, is coated with the above solution in the ordinary way (in a dark room, of course), the plates stood up to dry, and that is all. When dry they are ready for use, the person about to use them having been perfectly relieved from all trouble with silver bath, all trouble from washing, from all mess and inconvenience. The plates keep, with proper care, any length of time, and may, as we think, be developed at any time after exposure.

"Mr. Stillman is very enthusiastic upon the subject of photography, and has come to this country with the purpose of introducing this new article to our young men, anticipating for his favourite pursuit a great and gratifying extension, by thus eliminating from the practice of dry plate photography most of its unattractive details."

### Proceedings of Societies.

#### PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE first meeting of the session of this Society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, the 10th inst., Mr. J. SPILLER, F.C.S., in the chair. The minutes of a former meeting having been read and confirmed, the following gentlemen were elected members of the Society:—Sir Thomas G. A. Parkyns, Messrs. H. J. Burton, F. H. Chaffin, J. Hawke, J. C. Heaviside, D. L. Mundy, J. W. Smith, W. Street, H. P. Swaine, E. Viles, A. W. Wilson, F. M. Sutcliffe, A. Ford Smith, J. M. Young, R. C. Murray, V. Heath, J. S. Catford, W. Nicholson, C. Ferranti.

The CHAIRMAN congratulated the members on the excellence and success of the exhibition just closed, and added that, in addition to its other advantages, he thought it might be credited with directly or indirectly obtaining for the Society the nineteen new members whose names had been proposed. From various causes of delay and hurry, the first catalogue did not contain all the names; but the second edition contained the names of 103 exhibitors. Altogether he thought that in the holding of an exhibition they carried out a very important function of the Society.

Mr. SEBASTIAN DAVIS, as Treasurer, stated that the complete accounts of the Exhibition were not yet ready, but he might state, in general terms, that the receipts had been £55 14s., and that the expenses would not exceed that sum by more than from £20 to £25; so that the total cost to the Society for admission for members and their friends, and the catalogues distributed, would not exceed £25, a sum he thought well spent.

Mr. CHAMBERS wished for one or two explanations in connection with the Exhibition. The conditions, in the absence of any precise statements, were, it was understood, the same as in the preceding year; he wished to know how it was that certain coloured pictures were accepted. There were also frames of cards and cabinet pictures which were not in accordance with the conditions of last year, no abandonment of which had been published, and were still presumably in existence.

The CHAIRMAN explained that the coloured work, being in a frame with other interesting work, got admitted to some extent by accident; but, in truth, no conditions had been published.

Mr. WALTER BIRD said that the absence of conditions was an undoubted inconvenience. His own firm had been put to serious inconvenience by preparing contributions which they found were not admissible. He thought in future such conditions should be made quite clear.

The SECRETARY said that this year everything had been left in the hands of the hanging committee, who had used their own discretion.

After some further conversation on the subject,

Mr. B. J. EDWARDS asked if the circular of the Society, referring to the Crawshaw prizes, accurately stated the conditions. He believed that one prize was awarded wrongly if the announcement issued by the Society was correct, as the conditions in that announcement were not the same as those upon which he understood the awards had been made.

The SECRETARY said that he issued the circular by request of the President, and the conditions were copied from a back number of the Society's Journal. He was not aware that these conditions had been altered, and an error in dimensions of faces having occurred in the circular, Mr. Pritchard, in a letter to the NEWS, corrected it, and he understood him that in other respects it was correct. Mr. Pritchard also thought the matter of small importance, as the issue of the circular was too late to affect the production of competing pictures. He had, however, sent out post cards, and taken other means to correct the error in dimensions.

Mr. EDWARDS said if the circular was correct in stating that worked-up prints would be disqualified, he wished to express his protest against one award.

The SECRETARY said that this was a question altogether for Mr. Crawshaw and his jury. The Society had no control in the matter whatever, and not even official knowledge of the results.

Mr. JOHN CHAFFIN read a paper on the production of life-size heads, which will appear in our next.

After some conversation,

Mr. HOOPER asked if the lens used had any arrangement of diffusion of focus, as the pictures seemed to possess great depth of definition; and he wished to ask the distance between the lens and sitter. He regretted that he had not, in writing to Mr. Chaffin to read a paper, also asked him to bring one of the negatives with him.

Mr. CHAFFIN said the lens had no arrangement to produce diffusion of focus, but it had no very sharp focus anywhere, and was well suited for large heads. The distance between lens and sitter, so far as he remembered, was about four feet, and as in one case the size—seven inches—was larger than life, the distance between lens and plate was still greater.

Mr. EDWARDS, in answer to the Chairman, said the developer referred to by Mr. Chaffin was one which he had already published, consisting of sulphate and ammonia-sulphate of iron and a little copper salt.

Mr. CHAFFIN, in answer to a question, said he used gelatine in preference to albumen for a preliminary coating, because the latter was supposed to injure the bath. He found it recommended in one of the YEAR-BOOKS.

Mr. HART said albumen and gelatine, being colloid substances, could not reach the bath if the plate were properly covered with collodion, and none of the preliminary coating extended to the edges or back.

Mr. H. P. ROBINSON said as the mention of manufacturers' names had been freely introduced, he might, without impropriety, suggest to Mr. Chaffin that if he used one of Dallmeyer's 7 or 8D lenses he would be able very materially to reduce the time of sitting. He would find them much more rapid than the lens he described.

Mr. CHAFFIN had seen one of these lenses used in Hull, and the exposure was longer than his own.

Mr. ROBINSON said in his hands the exposure was very much less than that mentioned by Mr. Chaffin. He never thought of giving more than twenty or thirty seconds.

After a vote of thanks to Mr. Chaffin,

Mr. E. VILES read a paper on "Photography away from Home," which will appear in our next.

Mr. BLANCHARD pointed out that where negatives were intensified with iodine, pyrogallic acid, and silver, they were apt, during long printing, to become exceedingly dense and hard, from the action of light on the iodide of silver formed.

Mr. S. FRY referred to the undoubted advantages of the albumen substratum where it was fairly tried, the chief error of those who failed being, he believed, that they used too much albumen. As to iodine, he had used it for years. Negatives taken abroad had a little of the iodine solution poured over them, and if, on examination at home, they were found to need more intensity, they were simply placed in the light for half-an-hour. For washing plates and washing prints, on first removing them from the fixing bath as well, he found nothing so good as a very fine watering rose.

Mr. B. J. EDWARDS had tried the albumen substratum carefully, but with no good results whatever.

Mr. W. T. WILKINSON had used the albumen substratum for five years, and would not like to give it up. It saved trouble, gave cleaner results, and avoided all risk of losing the film. He used the white of one egg to sixty ounces of water.

Mr. CHAFFIN thought a common cause of failure in using preliminary coatings was not taking care that this coating was quite dry. If the plate were held before the fire, even when it appeared dry, it would often be seen that there had been some moisture.

Mr. WILKINSON, in outdoor work, always carried a spirit lamp to dry the plates before coating.

Mr. BEDFORD, in reply to the Chair, said he had never tried preliminary coatings, nor wooden baths lined with india-rubber. He generally used a glass bath, but had used ebonite without any disadvantage.

Mr. HOWARD had used ebonite for five years without trouble. When the surface got rough, or cracked-looking, a piece of sharpening stone easily rubbed it smooth. He had not succeeded with a substratum; specks, spots, and stains resulting from its use.

A MEMBER suggested that most of the troubles resulted from not using fresh eggs.

Mr. SYDNEY SMYTH used albumen with perfect success. He adopted a plan of coating recommended by Mr. Swan in the YEAR-BOOK, which he found the best method.

Mr. WERGE thought the best plan was to apply the albumen solution whilst the plate was wet. A solution containing the white of one egg, with thirty ounces of water, applied so, practically gave a coating like a solution with one egg in sixty ounces, and saved much trouble.

Mr. DAVIS powered a little on the plate, and spread it with a glass rod.

Mr. VILES said at one time he objected to the preliminary coating, but on one occasion the film of a beautiful negative floating off as he washed it, he resolved to conquer the difficulties of applying a preliminary coating. He had tried all the plans he had just heard recommended; but none he thought so easy and so efficient as the use of the Blanchard brush, applying the thinnest possible coating.

After a vote of thanks to Mr. Viles, and the reading of a letter from the new Belgium Society, the proceedings terminated.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

The fifteenth annual general meeting of this Society was held in the Hall, 5, St. Andrew Square, on Wednesday evening, the 4th inst., Mr. JAMES ROSS, Vice-President, in the chair.

The minutes of last general and previous ordinary meetings were read and passed, and Messrs. Wm. Nisbet, James Livingston, John Dick, John Eno, Robert Russell, and Charles Moxou were admitted ordinary members.

The SECRETARY then read the following report:—

*Report of the Council of the Edinburgh Photographic Society for the Year ending November, 1874.*

"In presenting this, the fourteenth Annual Report, your Council have much pleasure in congratulating you on the continued prosperity of the Society. During the past year the Society has maintained its character as one of the most energetic and useful institutions in connection with photography.

"During the year there have been held nine ordinary meetings, six outdoor meetings, and five popular evenings; all of which were well attended, and were characterised by fully more than the average amount of enthusiasm and usefulness.

"At the ordinary meetings the following papers were read:—

1. 'Experiences in Outdoor Photography,' by Serjeant-Major Perry.
2. 'Progressive Results of the Past Session,' by Dr. J. Nicol.
3. 'Action of Nitrate of Baryta on the Nitrate Bath,' by Mr. Tunny (two communications).
4. 'On the Preparation of Permanent Sensitized Paper,' by Mr. Turnbull.
5. 'Improved Lamp for Sciopticon,' by Mr. Turnbull.
6. 'On Polarized Light,' by Dr. J. Nicol, illustrated by Mr. Gilmour.
7. 'First Notes of some Experiments upon the Effect of Sunlight on the Colours of Pigments, with Introductory Remarks on the Propriety of Photographic Societies Discussing Artistic Questions,' by Mr. R. H. Bow.
8. 'Landscape Photography: Its Pleasure and Profits,' by Mr. W. Neilson.
9. 'Remarks on Dry Plates, with Special Reference to Lieut. Abney's Beer Process,' by Mr. W. H. Davies.
10. 'Spirit of the Journals' (two communications), by Mr. W. H. Davies.
11. 'On the Beer and Albumen Process,' by Mr. Turnbull.
12. 'Result of Experiments with Dry Plates Fumed with Ammonia,' by Mr. W. H. Davies.

"The five popular meetings consisted of—1. 'Demerara and Its People,' lecturer, Dr. Nicol. 2. 'Series of Views in North Wales,' lecturer, Dr. Nicol. 3. 'India: Its People, Scenery, and Antiquities,' by Dr. Iluter. 4. 'Series of Views of American Scenery,' by Mr. W. H. Davies. 5. 'China and the Chinese,' by Mr. J. Thomson.

"The outdoor meetings were held at—1. Winton Castle. 2. Ravelston. 3. Ainsfield Park, Haddington. 4. East Linton, Hales Castle, Whittinghame, and Biel House. 5. Collinton Glen and neighbourhood. 6. A second visit to Ravelston.

"It will thus be seen that the Society has shown its usual

amount of vitality, and done a good share of thoroughly practical work. During the year the Society has been subjected to the usual fluctuation in the number of its members, there having seceded from its ranks thirty, and been added to the roll seventy-four, leaving a present membership of two hundred and seventy-seven, showing an increase of forty-four members; the number being last year two hundred and thirty-three. From the Treasurer's Report it will be seen that the financial position of the Society is not, apparently, in a very satisfactory position. For this there are two reasons. First, it has been a custom since the commencement of the Society to let the accounts that were not rendered till after the general meeting in November lie over till the succeeding session. This informality your Council consider wrong in principle, and have therefore included the whole liabilities of the Society up to date. Secondly, there has been a considerable exceptional outlay for apparatus, &c., in connection with the popular evenings, which, of course, will not occur again for many years; and they have every confidence that the report of next year will show that the Society is in a healthy and prosperous condition.

"The following donations have been received during the year, viz.:—From Messrs. Polton and Son, of London, seventy-four photographs. From Serjeant-Major Perry, six photographs. From Captain Horatio Ross, a carbon enlargement of a study of dead game. From Mr. John Murray Gartshore, of Ravelston, five volumes photographic journals; also a handsome book-case in carved oak, a portion of the library at Ravelston, supposed to have been designed by Sir W. Scott. From the family of the late James Wood, an original copy of Rejlander's celebrated picture of the 'Two Ways of Life.' From Mr. Henderson, of Montreal, thirteen photographs. From Mr. Yerbury, two photographs of Biel House.

"Arrangements have been made for a series of popular evenings, which your Council believe will meet with general approval; and they confidently anticipate that the future of the Society will at least equal its past.

(Signed)

"R. G. MUIR, President.

"C. SINCLAIR, Hon. Sec."

The TREASURER also read his financial statement, and explained at length that the apparent shortcoming in the funds arose from the alteration of the termination of the financial year, and an exceptional outlay for apparatus, &c., for the popular evenings.

Mr. DOBIE, in moving the approval of both the reports, spoke of the good the Society had already done, but urged the members generally to greater efforts in furnishing matter for the ordinary meetings, as he felt quite sure that if every one would only do his duty in that direction, the usefulness of the Society would be much increased.

The reports were unanimously approved.

The meeting then proceeded to elect the following office-bearers:—*President*—Dr. John Thomson. *Vice-President*—R. H. Bow. *Treasurer*—Thomas Pringle. *Hon. Secretary*—E. R. Yerbury, 3, Hanover Street. *Corresponding Secretary*—Dr. John Nicol, 4, Dundas Street. *Auditor*—A. T. Niven. *Lecturer*—Dr. John Nicol. Members of Council in room of those retiring by rotation—R. G. Muir, Alexander Matheson, David Aird, John Bashford, and James Howie, Jun.

On the motion of Mr. DAVIES, seconded by Mr. PANTON, it was resolved that in future candidates for admission as ordinary members be required to deposit with the Secretary the amount of their annual subscription, along with their application, such deposit to be returned in case of non-election.

Dr. THOMSON, in thanking the members for his election to the office of President, said:—

"Gentlemen,—I rise to thank you for the honourable position in which you have placed me, by your votes this evening, as President of the Society; and my thanks are all the more sincere and heartfelt on account of the handsome manner in which you have conferred that honour, having been unanimous in your election. But whilst I thus thank you, I cannot at the same time congratulate you on the choice which you have made, for I feel, and very painfully too, my own unfitness for the office, and I am persuaded that you might have made a much better selection from among the other members of the Society. When I look around me I could point out several, who are men of talent, with refined taste and cultivated intellect, and who combine with these qualifications an ease, grace, and pleasantness in giving expression to their thoughts, with the happy knack of being able to throw in a touch of humour on fitting occasions, so as to soften the hardness and rigidity attendant on scientific discussion; just as the photographer can, by an experienced and artful touch, soften down

his picture when the contrast of light and shade is too strongly marked. These members have also an intimate acquaintance with photographic literature, and possess an extensive knowledge of those sciences on which are based the principles of our beautiful art, as well as show great manipulative skill and dexterity in working out the details of the various practical processes. But the choice has been made, and it now rests with us to make the best of a bad job. On my part I promise to place myself entirely at the service of the Society; and I hope that with the co-operation of, and the assistance which I expect to receive from, the able staff of office-bearers (who are really the working men) we shall be able to pull through the ensuing year. I am the more encouraged to hope for this favourable result from the experience I acquired when attending your meetings last session. I had then the satisfaction and gratification of witnessing that your general business and discussions were conducted in a quiet, orderly, and gentlemanly manner, giving no occasion for the interference of the President, but rendering his office almost a sinecure. I hope that there may be as little reason for action on my part during the session on which we have entered. And now, gentlemen, I have to request a favour of you, and that is, that all of you put forth a strong effort to advance the progress of our favourite art, and, by contributing largely to the general fund of photographic knowledge, not only to maintain our Society in the high position which it has taken among the kindred institutions of this country, but to raise it a step or two higher in the scale of excellence and rank."

Mr. YERBURY then said:—

"Gentlemen,—I rise to thank you for the very high honour conferred upon and confidence placed in me, in appointing me to so high a position in this Society—a Society so large, whose influence is not confined to the name it bears, but to its world-wide influence; and to hold so high a position in such a Society is, I assure you, gentlemen, an honour I feel proud of.

"I thank you also for the confidence reposed in me by placing so much of the Society's interest in my hands—an honour I shall strive to merit by careful attention to the duties devolving upon me. I enter upon the task of the secretaryship with some amount of timidity, knowing the very large amount of work that is involved in it. I go forward in the confidence that I have in my fellow office-bearers, whose co-operation I feel certain of from the experience I have had in the past while a member of Council. I trust, therefore, with their good support to fulfil the duties to the satisfaction of the Society.

"Accept, then, my sincere thanks for the very great honour you have conferred upon me, and rest assured nothing will be left undone by me that will help to promote the interest, prosperity, and reputation of the Edinburgh Photographic Society."

Votes of thanks were then given to the retiring office-bearers, council, and chairman, and the meeting adjourned.

#### THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The ordinary monthly meeting of the Board of Management was held at 174, Fleet Street, on Wednesday, November 4th, Mr. GANLY in the chair.

The minutes of the previous meeting having been read and confirmed, Mr. J. B. Hall was elected a member of the Board, vice Mr. Bird, elected chairman. The Relief Sub-Committee read their report, which was received, and ordered to be entered upon the minutes. To induce photographers in the provinces to become local secretaries, it was resolved "that a commission of ten per cent. be allowed to local secretaries upon all subscriptions and donations collected by them."

The SECRETARY announced that the following gentlemen had promised donations of photographs for the Art Union Distribution, viz.:—Mr. Bedford, Mr. Blanchard, Mr. W. England, Mr. Hubbard, Messrs. Fradelle and Marshall, A. and G. Taylor (at least £10 worth of their Albert Memorial series, as well as a donation), Spencer, Sawyer, Bird, and Co. (two of their 30×24 enlargements in the exhibition), A. and J. Bool, Mr. A. Ford Smith (a framed photograph like No. 49 in the exhibition, and some other landscape), Mr. J. M. Young (any photographs in his or previous exhibitions the Board may select), Mr. H. Whitfield (the three framed pictures, Nos. 76, 77, 78, in the exhibition, and six landscape photographs), Mr. F. M. Sutcliffe, Mr. J. Brier, Jun. (eight 12×10 landscapes, received), Mr. J. A. C. Branfell, Mr. F. Howard, Lieut.-Col. Roche, Mr. B. J. Edwards, Messrs. S. and E. White, Ronch and Co., Russell and Sons, Mr. Werge (No. 215 in the exhibition), and Mr. E. Fox; so that there was every indication of a successful drawing.

The form, date, and place of general meeting were

then discussed, the Board being of opinion that after the election of officers, &c., it would be as well if some kind of an entertainment could be arranged. Several of the members present were able to promise for themselves and friends assistance towards an entertainment. It was then resolved that the general meeting, to be held in January next, after the despatch of business shall resolve itself into a *conversazione*, and that the prizes in the Art Union distribution shall be exhibited, together with a lantern exhibition, and a musical entertainment to be provided by members and friends. Art Union tickets to admit to this entertainment, as well as giving a chance in the drawing.

Mr. GANLY then vacated the chair (which was taken by Mr. Ashmau) and tendered his resignation as Deputy Chairman of the Board of Management, on account of leaving England for India.

Mr. W. T. WILKINSON expressed his regret at losing Mr. Ganly, as he had been connected with the Association since it had first started. At the same time he hoped that Mr. Ganly would like his appointment in India, and would have a pleasant journey. A vote of thanks to Mr. Ganly was carried by acclamation, all members wishing him God speed on his journey.

Mr. GANLY thanked the members for their kindness, and said that although he had resigned his office, he was still a member of the P. B. A.

W. T. WILKINSON, Secretary.

#### PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.\*

At the September meeting of the Photographic Section of the Institute Mr. H. J. NEWTON read a paper on "A Rapid Dry Process" (see p. 500, Oct. 16).

Mr. MASON.—Before Mr. Chapman went into the country, I called one evening at the Rutherford Observatory to close up some astronomical work, and found him experimenting with collodions with his actinometer, which he exhibited here some years ago; and among the samples he was trying a collodion containing chloride according to a formula given by Mr. Newton. He did not tell me the exact formula, but found the collodion was not so sensitive as the collodion which he used for star work.

The PRESIDENT.—I am not prepared to say that for in-door work the chloride is as advantageous as it is for dry plates. Whatever collodion Mr. Chapman may have been trying, he uses a collodion very near that formula without the chloride, and he uses no iodide nor bromide except cadmium. The proper way to test it would be to make a collodion with the same chemicals, some without the chloride and some with, and, in trying the two, to flow the plate half with one sample and half with the other, and expose them together.

Mr. MASON.—This method of working with the scale I consider an important test. It will be remembered that some years ago I read a paper in which I claimed that we must fall back on artificial light, where we can get a constant amount of actinic force, because there are changes on a perfectly clear day caused by varying strata in the atmosphere containing absorbents, which change the nature of the light materially.

Mr. PARKHURST.—How rapidly would such changes occur?

Mr. MASON.—Within a very few minutes. I have observed a very material change in the course of five minutes.

Mr. PARKHURST.—I have found when making photometric observations of the stars on evenings which were apparently perfectly clear, that there would sometimes be very appreciable changes in their brilliancy in the course of a few minutes.

Mr. J. B. GARDNER.—I have tried the collodion from the formula given, and it worked quicker than the collodion I had been using, and consequently I have used it ever since. I did not in any instance use any iodine, but found that the collodion invariably changed its colour to a certain extent, and there was no need of colouring with iodine.

Mr. THOMAS.—If your cotton was fumed you would require the iodine.

Mr. GARDNER.—If the colour is light it works well; it is a light straw colour, and grows darker.

The PRESIDENT.—I have some which has been made nearly a month, and it is as white as water.

Mr. CHISHOLM.—The way I have been in the habit of making my collodion is, to dissolve the cotton in ether and alcohol, reserving a certain portion of the alcohol for dissolving the salt—the iodide or bromide. They keep perfectly white for a year in that way; but when they are put together, the next day they are straw colour, and keep growing darker. I inquired of Mr. Anthony the cause of it, and he says that if you dissolve cotton in alcohol and ether it will, in time, become acid, but will not show it until you put the iodide with it. It keeps turning red after putting them together.

\* *Anthony's Bulletin.*

Mr. THOMAS.—It ought not to with cadmium.

Mr. CHISHOLM.—I used Anthony's No. 1 cotton, and the ether was made expressly to order for me, and there was no alcohol with it.

Mr. THOMAS.—If you want to keep it colorless you can do so, by putting in a strip of metallic cadmium.

Mr. MASON.—I noticed in a recent communication of Dr. Vogel that he had given a formula for collodion which he had used for some years successfully, and he received a letter from an eminent photographer who had used the formula and had been successful with it; and, in corroboration of his statement, he sent plates which Dr. Vogel declares were enough to make a man blush to have recommended such a thing. The gentleman sent him other plates, which were very brilliant, made exactly in the same way except the collodions. Soon after Dr. Vogel met this gentleman, and found that his method of iodising the bath was by dipping the plate, and letting it stand over night, which was sufficient for his own collodion, but not sufficient for Dr. Vogel's formula. Dr. Vogel mentions that as an important item. He iodises his bath by forming iodide of silver, and adding it to the solution.

Mr. THOMAS.—I never think of such a thing as iodising a silver solution.

Mr. MASON.—I always add an amount of iodide of silver. I have tried the method of iodising the bath with the plate, but never found it work as satisfactorily.

The PRESIDENT.—When I make a new bath, I add the iodide of potassium to the solution.

Mr. THOMAS.—I do not think I make a new bath once in seven years. I use them pretty acid. I find that a silver solution will always correct itself. The iodide of the plate is down in the bottom of my bath, where it is like mud.

Mr. MASON.—I take pure metallic silver, and add to it a sufficient amount of nitric acid to dissolve it; then add to that water sufficient to make the strength I desire; then put it in the evaporating dish, and boil it; then I filter it, and render it acid by the addition of nitric acid, and put it in the bath, and I am ready at once to go to work.

Mr. THOMAS.—If the bath is new it will work too rapidly. I never found my bath out of order.

Mr. MASON.—Can a silver solution that has never had iodide of silver in it be used to make a negative?

Mr. THOMAS.—Yes; I make it quite new, and never think of such a thing as putting in iodide of silver. In making collodion, if you do not put the bromide in first, it will not do for me. I would never use a drop of water that was not boiled.

The PRESIDENT.—I have directed in my formula that the bromide should be put in first.

Mr. CHISHOLM.—The bromide of potassium always worked clearer with me than any other bromide.

Mr. MASON.—When I commenced working the collodion process in 1854, we were very careful about adding water to the collodion, not to put in more than was necessary. Afterwards I made a series of experiments with collodion to which I added as much as four ounces of water to twenty ounces of collodion, and made a perfectly homogeneous film, which would bear examination under the microscope. I was surprised at the amount of water which could be used in collodion, and give a beautiful film. On the other hand, collodion with very little water in it will sometimes give a very bad reticulated film.

Mr. THOMAS.—The cotton was made at a very high temperature, and you cannot use much water with that. I use cotton made at a low temperature.

### Talk in the Studio.

PORTRAIT OF THE LATE PRINCE CONSORT.—We have recently seen an interesting application of photography in a portrait of the late Prince Consort. Possessing a small negative which he had taken of His Royal Highness, which was not sufficiently perfect for ordinary printing, Mr. Rejlander felt that there was in it a nobleness and truth of likeness rarely seen in the Prince's portraits. He secured, therefore, a slightly indicated outline of it in an enlarged form, and proceeded to work it in crayon and sepia, finally finishing with varnish, and giving the effect of a fine oil painting in monochrome. As a work of art it is admirable, and as a portrait it possesses a nobility and dignity, and an intellectual thoughtfulness, we have not seen in any other portrait of "Albert the Good."

COLOURED ENAMEL PORTRAITS.—Various attempts have been made to combine tinting or colouring with the effective style of enamelling card and cabinet portraits now in vogue;

but the great difficulty of moving and spreading the applied tints has stood seriously in the way of success. We have seen some examples by Mr. Leslie in which this difficulty appears to have been overcome, the prints being brilliantly tinted, and subsequently enamelled without injuring the colours. The result depends, we understand, upon the use of a vehicle with the colours which protects them from softening and spreading when in contact with the aqueous solution of gelatine. The result is very effective.

**A STARTLING INVENTION.**—If our readers are not "startled" with the following, which appears in the *Pictorial World*, they will at least be amused:—"Almost simultaneously with the opening in London of the Exhibition of the Photographic Society of Great Britain—which we may notice more fully next week—and the revival of attention to the important position photography is attaining in the production of *genre* and original works of art, there comes the intelligence of a photographic invention so startling in its power for good or evil that we can only compare it to the wondrous lamp of Aladdin, or to the feats of genii in Eastern story. An Englishman—for it is an English invention this time—has discovered a method of fixing the image of an object on a sensitized plate not more than half an inch in diameter, an impression from which can be afterwards enlarged to the necessary size. The plate is fixed into an ordinary locket or keepsake hanging from a watch chain, and can be suddenly exposed, by a touch of the finger, on entering a room, and an image taken of a picture or a person without any one besides the operator being aware of it! The ingenious method by which the exact place, person, or picture is brought into focus by first casting a soft ray of artificial light from this wonderful locket is the important part of the invention, which we are not at liberty to mention further in detail at present. Whether or not such things can be done to any purpose, it is high time that artists and photographers who produce original pictures should look to the immediate protection of every work of art or new design by entering them at Stationers' Hall. As the law of copyright stands at present, it is, we believe, the fact that from the moment an artist opens his studio door to the photographer, for him to take a private copy of his painting before the work is sent away for exhibition, his property in his own composition is in jeopardy if he has not taken the precaution of protecting it—a ceremony costing *one shilling*. But if this marvellous invention we have spoken of, and of which the public will soon hear more, is to be perfected as easily as we are assured it will be, no picture can be exhibited in a public gallery, or even in a shop window, without risk of being copied on the spot. Of the numberless uses—practical and amusing, good and bad—to which such an ingenious contrivance may be applied, we will only now mention one—the foremost, we understand, in the inventor's mind—viz., as an instrument in the hands of the detective police of the metropolis." The dangers to copyright suggested, even if such an instrument existed, are all moonshine.

**SELLING INDECENT PHOTOGRAPHS.**—In a charge against William Burton, described as a middle-aged man, of Holywell Street, it appears, according to the evidence of Inspector Harnett, as reported in the *Daily News*, that the accused, in addition to some twenty or thirty books of an indecent character, had in his possession some negatives, which were found at the bottom of the house. The prisoner said that they were brought there by a man named Harrison about a fortnight ago, for safety. They were examined, and were found to be of a most indecent character. There were ninety-one glass negatives. Witness had known the prisoner for some time by the name of White.—Sergeant Kerley, detective E division, said that, having received instructions from Superintendent Thomson, he went with inspector Harnett to 32, Holywell Street, on Saturday last. He went down stairs, accompanied by a female who was told by the prisoner to go with witness, and there in a cistern in the kitchen he discovered a false bottom, and in it a number of negatives.—Several objections were raised, but Mr. Vaughan considered there was sufficient evidence to make out a *prima facie* case.—The prisoner was then committed to the Central Criminal Court, and Mr. Vaughan said he would accept substantial bail, the prisoner in £500, and two others in £250 each.

**DEALING WITH BLISTERS.**—A correspondent of *Anthony's Photographic Bulletin* says:—"My plan is as follows. We will suppose the prints in the hypo solution, and blistered. Now we take them from the hypo, and pass them through one or two changes of water, not leaving them very long in either.

Now take two sheets of blotting paper, and cover one of them with prints from the water just so that they do not lie one on the other, and then, with the other blotter on top, rub all the water out of the prints, and you will have rubbed the blisters down. Now lay the prints thus rubbed between sheets of unprinted printers' paper, and let them get nearly dry, when you can put them again into the water, and wash them as long and as hard as you wish, and you will see no more blisters on those prints. I have yet to lose the first print treated as above. As to their permanency I cannot say; but thus far they do not show the least sign of injury."

## To Correspondents.

**ONE WHOSE AMBITION IS TO EXCEL** sends, for our opinion, a transparency on a plate prepared in accordance with Captain Abney's instructions for the albumen-beer process. It is very excellent: clean, soft, delicate, brilliant, and of an admirably rich tone. Our correspondent adds that he has succeeded with the albumen process in obtaining fine transparencies, but he does not state which of the albumen processes. He has also found the instructions of Mr. Davies for mounting without cockling answer admirably.

**C. R.**—The address in question frequently appears in our advertising columns: it is No. 1, Budge Row, Cannon Street.

**J. J. S. G.**—First try the bath, and ascertain if its working qualities are injured; and if this be so, then add a portion of fresh silver solution, which will probably restore working conditions. 2. The legitimate or fair time in which a plate can be worked depends much on the state of the weather. We should say, however, that twenty minutes was ample time for completing a quarter-plate negative, from coating the plate to fixing the negative. In summer weather it would not be difficult to do it in less time. 3. We will have pleasure in stating your judgment upon any examples sent.

**GEORGE.**—Coralline is a preparation of aniline. We do not think it likely that provincial chemists will keep it; but we can scarcely suppose that photographic chemists in town will tell you that they know nothing of it. If you have tried all the photographic chemists in town, write to Messrs. Mawson and Swan, at Newcastle-on-Tyne.

**PIERRE REVON.**—So far as we can judge from some personal experience, and from the reports of those who have carefully tested the matter, there is an advantage in rapidity and in excellence gained in fuming sensitive albumenized paper with ammonia, whether in direct enlarging operations with the solar camera, or contact printing from the negative. We should not, however, with any commercial sample of paper, use a bath of more than ten or twelve per cent. 2. The use of carbonate of ammonia in the fixing bath does undoubtedly, we think, give advantages in securing perfect fixation, and in preventing acidity and decomposition of the hypo bath. Washing with salt and water is not necessary; but it is wise always to wash the print well, or even immerse it in a weak alkaline bath after toning, to avoid carrying anything into the fixing bath which might tend to decomposition. 3. So far as we know, No. 3 on your list stands highest.

**CORNWALL.**—We do not remember the price, nor maker's address.

**ASSISTANT OPERATOR.**—The coarse, morocco-like texture at the lower end of the plate, with a slight tendency to reticulation, is due partly to the collodion and partly to the manipulation. The collodion is probably somewhat thick and glutinous in texture, and it has been immersed in the bath before the film was well set. At this season of the year, the weather becoming colder and the atmosphere damper, the collodion requires more time to set properly before immersion in the silver bath than in summer.

**F. G. R.**—We presume that any camera maker will be able to apply the small inside shutter as a substitute for the cap of the lens. In any case you can apply to the gentleman who exhibited that mentioned at the South London meeting.

**B. D.**—We saw the paragraph in question. The ownership of the negative has been for some time a moot point. Some hold that by the last Fine Art Copyright Act the copyright of a portrait taken in the ordinary way of business belongs to the sitter; but even then the negative itself would belong to the photographer. Others hold that the copyright falls to the ground altogether without an agreement in writing; but then, also, the negative belongs to the photographer. This is our own impression. See some remarks on another page.

**G. K.**—A good substitute for the ground glass may be made by coating ordinary glass with a matt varnish; or if that is not at hand, a plate collodionized and excited may be used; or starch, applied warm to a plate, will form a fair substitute; or crystal varnish with a little white wax added. There are also other methods of producing a similar substitute.

**JOSEPH BYRNE.**—Thanks; we shall have pleasure in examining and reporting.

**G. WILLIS** and **R. W. ALDRIDGE** in our next. Several Correspondents in our next.

## The Photographic News, November 20, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO. THE AUSTRIAN NORTH POLE EXPEDITION—A NEW APPLICATION OF KAOLIN.

*The Austrian North Pole Expedition.*—Travellers often tell strange tales, we know, and it is not always the more truthful parts of them that obtain most credence. The story of the sailor lad, whose wonderful experience his mother was quite ready to believe in until he came to his description of flying fish, is one which finds its parallel every day, and no wonder, therefore, when travellers find their friends doubting realities, that they should resort to the marvellous and imaginative to make their story interesting, if it is nothing else. The popular idea of the Arctic regions and the North Pole will, we think, be somewhat shaken by the photographs that come to us from Vienna of the Austrian Polar Expedition. The charming pictures taken by Lieut. Chermiside, R.E., last year, when attached to Mr. Leigh Smith's Northern expedition, gave us a good idea of what the Arctic regions are under favourable circumstances. One could almost trace colour in some of them in the glow of light upon the horizon, and behind the rugged headland stretching far into distance, which afforded such capital pictures for the camera. The scenery further north, such as it is shown to us by the Austrian pictures, is far less picturesque than the country depicted by Mr. Chermiside. The expedition, as our readers know, penetrated further north than any other, with the exception of an American one under Hall, whose journeyings, by the way, are not very clearly defined, the most northern point reached by Lieut. Payer being 82.5 degrees, and he observed land as far north as 83 degrees, or thirty miles further. In this kingdom of desolation the ice fields extend in all directions, the flat mountainous surface of white being represented in the pictures brought home with terrible reality. The ship had to be abandoned altogether, because it became hopelessly surrounded by ice fields; and certainly the picture of the vessel in this position shows that the explorers were perfectly right in doing so. They started north in August, 1872, and were unfortunate enough to become attached to the ice and frozen to the main land very shortly afterwards. They remained with their vessel fourteen months, until the commencement of the present year, and during this period a small party, commanded by Lieut. Payer, set out and explored the country more to the north. They called the northern wastes they traversed by the name of Franz Joseph Land, a wild rocky country where moss and lichens are the only representations of the vegetable kingdom. The party has not brought back with them a photograph of the North Pole itself, reared on end, with the Austrian colours flying, which would perhaps have been convincing proof to Mrs. Grundy, who, like the sailor boy's mother, requires something confirmatory of her own established notions; but the pictures go far to confirm their story. Unable to use their vessel to return, they turned the ship boats into sledges, and in this way reached the Nova Zembla Islands, where a Russian vessel providentially found them and bore them to Norway. It has been suggested by Mr. Glaisher, we believe—who, as our readers know is the most experienced scientific aeronaut living—that the next Polar expedition should carry out with it a balloon with which it could make an ascent at the most northern point reached, and thus be able to see, perhaps, a hundred miles farther on. If, for instance, Lieut. Payer had been provided with a balloon in the present instance, he would have been able, supposing the weather were clear, to have seen as far as the North Pole, and could have told us whether land existed in those regions, or whether there was an open sea, as some affirm. There would be some difficulty, perhaps, in taking out apparatus for evolving gas to fill a hydrogen balloon, but in such a cold climate the Montgolfier, or fire balloon, might, perhaps, be made use of. Mr. Glaisher

tells us that in one of his ascents in England he was able to see the coast of Norfolk and that of Wales at the same time, the whole breadth of England being visible at his feet at one time, as if it were a gigantic map. However, such a lofty ascent as this would not be necessary in order to see to the North Pole by any expedition going so far north as that of Lieut. Payer's. Another expedition has already been formed at Vienna to start next summer, and this is to be supplied with observing instruments, including cameras of the most improved description; but the question of a balloon equipment is obviously a matter that will require further consideration.

*A New Application of Kaolin.*—The photographer's old friend kaolin, or china clay, is to be used for other purposes besides that of clarifying muddy silver baths, a service which it discharges to the great satisfaction of us all. Wine growers and merchants have found that its fining properties may be made use of with great benefit in clearing wines. A quantity of kaolin, amounting to about a half per cent. of the weight of wine to be operated upon, is mixed with a small quantity of wine, so as to form a pasty mass, and this is then added to the liquid that requires fining. The impurities in suspension are caught up by the finely-divided clay, and thrown down with the latter in the form of an insoluble deposit, which may be decanted off, or, if need be, filtered from the wine. It is stated by those who recommend kaolin for fining wines that should the clay contain iron as an impurity, it must be digested with dilute hydrochloric acid, every trace of acid being, of course, washed out again before the material is employed for clarifying. So that if any photographer is troubled with elaret or sherry becoming turbid, he need merely have recourse to his ordinary photographic clearing agent to make it all right again. So far as we ourselves are concerned, we should prefer employing a clay with an alkaline rather than acid reaction.

### THE "GLACE," OR ENAMELLED PHOTOGRAPH.

HOW TO DO IT.

BY I. B. WEBSTER.\*

THE glass upon which the enamelling is to be done must be scrupulously clean. Plate-glass, free from scratches, is the best, although good photograph glass will do if not scratched. Blisters in the glass hurt nothing. After it is thoroughly clean, sprinkle over it, by means of a five-cent pepper-box, "powdered talc" (or French chalk), and with a tuft of cotton rub in a circular motion (carefully going over the whole surface) until no trace of the chalk is perceptible. Do not rub heavily. The chalk gives a surface to the glass that assists in the lifting the enamelled print from it. Now flow the plate with collodion made as follows, viz.:—

Ether ... ..	4½ ounces
Alcohol ... ..	3½ "
Cotton to thicken (say from 5 to 7 grains to the ounce of solution), and 24 drops (or minims) of castor oil.	

When this flow is dry, apply the prints, face down, after immersing them in a gelatine solution made as follows:—

Cox's gelatine ... ..	1 ounce
Water ... ..	8 ounces
Glycerine... ..	50 drops.

Add the gelatine and glycerine to the water, and let it stand over night, when it will be ready for use after filtering, which can be done by warming sufficient to make the solution limpid. Allow the prints to remain in this solution about five minutes before laying them on the collodionized glass, and then pass a gum roller lightly over them to press them tightly to the glass, and also to remove the surplus gelatine. After the prints are nearly dry they are ready for the mounts. For this purpose light "Bristol-board"

\* Philadelphia Photographer.

is best. Use the gelatine solution for mounting, and mount on the glass as the prints lay. The whole thing must be perfectly dry before an attempt is made to remove them from the glass. When they are dry run a knife-blade around the edge to start them up, and if thoroughly dry and the work properly done, they will come off all right. I forgot to say in the proper place that it is a good idea to lay upon the back, after the mounts have been applied, a weight of some kind (say a heavy piece of glass), which should remain there for an hour at least. This assists in securing a complete contact to the print. At the end of an hour remove the weight and leave the print, back up, until perfectly dry all through. Sometimes they start off without help, which shows perfect success. Remember that "careful manipulation" is the only surety for success. A little experience will enable any one to perform this operation well.

#### ELIMINATION OF HYPOSULPHITE OF SODA FROM PAPER PRINTS.\*

REPORT OF COMMITTEE.

The committee appointed for the purpose of testing Mr. Henry J. Newton's method of removing hyposulphite of soda from photographic prints by means of acetate or nitrate of lead would respectfully report:

That they have had four meetings since their appointment (all the members of the committee being present except Mr. D. C. Chapman), and have made a series of experiments both in foreign and domestic albumenized papers.

The committee, believing the permanency of silver prints of vital importance to every photographer, they have neither spared time nor expense in trying to solve the problem for which they were appointed. While they set out with the belief that there were many causes why photographs have never been made positively permanent, they are still under the impression that there is nothing so likely to ruin them as the agent used for making them unchangeable.

The committee in their experiments have demonstrated in many ways the wonderful tenacity with which the hyposulphite clings to albumenized silver prints, and thus arrived at the conclusion that perhaps not one picture in a thousand was ever absolutely free from it. If, therefore, Mr. Newton's mode of removing it was true and practicable, it should be proven and made known to every photographer who takes even the smallest interest or pride in the permanency of his work. And all due praise should be rendered to him who had removed one of the chief stumbling-blocks in the way to the development of an art, not only highly useful in its tendencies, but designed to elevate the æsthetic status of humanity. At one of the meetings of the committee it was determined by careful experiments that of all the known tests for detecting the presence of hypo, the starch and iodine was the most reliable when freshly and properly prepared. By this test not even the 250th part of a grain in an ounce of water, or  $\frac{1}{125000}$  part, escaped detection.

It was also demonstrated by experiments that the acetate or nitrate of lead was the best known means of decomposing the hypo. Prints that were washed after coming from the lead solution in simply four changes of water showed no trace of hypo, while those washed in running water for twelve hours or more (without the lead solution) were still found contaminated with it.

The committee also followed minutely the entire process of silvering, printing, and toning as practised by Mr. Newton, which is as follows:—

##### *Silver Bath for the Paper.*

Water	...	...	...	...	1 ounce
Nitrate of silver	...	...	...	...	40 grains
Nitrate of ammonia	...	...	...	...	20 "
Nitrate of lead	...	...	...	...	5 "

\* *Photographic Times.*

Aqua ammonia sufficient to make the bath slightly alkaline. The paper fumed ten minutes, and a trifle overprinted.

##### *First Washing Water.*

(As originally published by Mr. H. T. Anthony.)

Water	...	...	...	...	1 gallon
Acetic acid (No. 8)	...	...	...	...	$\frac{1}{2}$ ounce

Followed by three changes of plain water.

##### *Toning Bath.*

Water	...	...	...	...	40 ounces
Commereial chloride of gold	...	...	...	...	15 grains
Carbonate of magnesia	...	...	...	...	40 "
Saturated solution of bicarbonate of soda	...	...	...	...	$\frac{1}{2}$ draehm
Tartrate of antimony	...	...	...	...	30 grains

(Or  $\frac{1}{2}$ -ounce of a 60-grain aqua solution)

Saturated solution of lime water ... 1 ounce

This bath, when used, to be reduced with water to suit the speed with which it is desirable the prints should be toned.

##### *Fixing Bath.*

Water	...	...	...	...	8 ounces
Hyposulphite of soda	...	...	...	...	1 ounce

##### *Bath for Eliminating the Soda.*

Water	...	...	...	...	30 ounces
Acetate of lead	...	...	...	...	30 grains
Acetic acid (No. 8)	...	...	...	...	1 draehm

In using this formula the committee proceeded as follows:—

After the printing the pictures were soaked in the acid solution ten minutes. They were then washed in three changes of water (not exceeding a gallon to a sheet) and placed in the toning bath, which was compounded in the following order: Thirty grains of chloride of gold dissolved in twenty ounces of water, with carbonate of magnesia sufficient to neutralize the solution. Then was added the bichlorate of soda, lime water, tartrate of antimony solution, and finally water sufficient to make up the bath to eighty ounces. The pictures, after being toned and fixed, were first washed in three changes of water (which took about three gallons in all) and then placed in the lead solution, where they remained from five to ten minutes—thirty ounces of solution being used for each sheet of paper (though much less than this would have answered the same purpose). The final washing of the prints was completed by passing them through four changes of water, thus consuming much less time and less water (viz., one gallon to a sheet) than is commonly used by most of the ordinary modes of treatment.

The committee found that the fourth washing water showed no trace of hypo by the test they adopted, and therefore believe prints treated with the lead salt perfectly free from the often deleterious effects of the fixing bath. But, to further prove whether they are right in their conclusions, they propose to subject the prints, herewith presented, to such tests as may best be devised for proving their permanency.

#### AWAY-FROM-HOME PHOTOGRAPHY.

BY EDWARD VILES.\*

THE series of views in the late Exhibition, Nos. 140 to 151, about the production of which I am asked to furnish some particulars, were all taken by the ordinary wet-collodion process, and at a considerable distance from my residence. Nos. 141 and 146 were prepared and developed in one of Murray and Heath's box-tents; Nos. 140, 142, 144, 149, 150, and 151 in a Clarence carriage, temporarily adapted for the purpose by covering the windows with orange paper; and the Welsh views, Nos. 143, 145, 147, and 148 in an omnibus. So far as manipulation is concerned, I am not aware that any difference can be detected

\* Read before the Photographic Society, November 10th.

is the general idea that the more refined conditions for film work are not their difference in the different and same conditions. It would be better to have a good and uniform condition for general use than to have the best of photographic conditions at a certain time, leaving the camera with an inferior general condition of work. This, one of the most important considerations, is a problem of which I wish to write in order to get a better idea of the way of the film work—what makes it so easy to do.

In order to do it is better to have a good and uniform condition of working with the camera of working the camera than to get the best film. In making the work of which nothing can be done after the film has been developed, the best is to get the best and the working camera than to have the best camera with a good film. The camera is a good and uniform condition of working with the camera of working the camera than to get the best film. In making the work of which nothing can be done after the film has been developed, the best is to get the best and the working camera than to have the best camera with a good film.

for an indefinite period. When away from home on a tour, I simply wash and sun-dry the plates as above, and leave them till my return, which may be in a week, a month, or longer. Some negatives I took in Wales last August now remain in the plate-box in this condition. The convenience attendant upon this proceeding scarcely requires pointing out.

I always fix in a wooden tray containing a saturated solution of hyposulphite of soda. Before the negative is immersed in the fixing bath, however, it must be well wetted all over under the tap, otherwise destructive markings will ensue. When thoroughly fixed, wash the plate well with hot water, which will effectually get rid of all traces of hyposulphite in less than half the time that cold water would require. But it is advisable to give a final rinse with cold water.

Upon now holding the negative up to the light, an accurate opinion can be formed as to its qualities. The colour will be brownish, and, in all probability, it will be sufficiently dense to yield a good print, although to the eye it may look somewhat thin. But should it appear that more intensity is wanted, prepare the following solution:—

Iodide	...	...	...	20 grains
Iodide of potassium	...	...	...	40 "
Water	...	...	...	1 pint

Take sufficient of this port-wine-looking mixture, and with one sweep flood the plate; keep it flowing to and fro for a minute or so. It will sometimes happen that this operation will produce sufficient intensity, for it clears the shadows and produces contrast. Its object is to prevent all danger of fog or stains in subsequent operations, and it serves to facilitate the action of the intensifier, which is thus made:—

Pyrogallie acid	...	...	...	45 grains
Citric acid	...	...	...	10 "
Glacial acetic acid	...	...	...	1 ounce
Rain water	...	...	...	20 ounces

Now go into the dark room and pour sufficient of the above into a developing cup and flow well over the plate, and leave it there; then add to the solution remaining in the measure a few drops of a twenty-grain solution of nitrate of silver (more or less, according to the degree of density needed). Begin with a little; more is easily added afterwards. Give the measure a circular shake, and drain into it the solution that remains on the plate. By this means a complete and intimate mixture is obtained, and a smooth, even flow over the negative ensured. Pour on and off the negative until the requisite depth is reached. Take care not to make the negative too dense, for the action of the intensifier is very energetic.

I recommend the above method to all those who find a difficulty in getting enough density. It is the result of a patient trial of all the formulæ which have been published during the last half dozen years. It is preferable to intensify after fixing, because one is so much better able to judge of exact density gained.

After a thorough and final washing, the plate is ready for varnishing. I prefer to dry by a clear fire, and put aside until cool enough to receive the varnish. The glass should be just warm enough to prevent the varnish from chilling, and no more. The warmth should be uniform all over. By keeping the plate cool the varnish flows better, and lines are not produced at the edge of the wave of varnish should its continuous flow be momentarily arrested. If one of these circular hair-like marks appears, keep the plate horizontal for a longer period than usual, and the mark will generally disappear; at any rate, sufficiently so not to show in the printing. I use Mawson and Swan's extra hard varnish, because it neither becomes sticky nor peels off, which is more than I can say of any other varnish I have tried.

Having now described the chemical operations, this paper comes appropriately to a conclusion. It was my intention to add some hints upon the mechanical work in

the field (the result of the experience gained in taking a considerable number of negatives), but I find space prohibits it. Should there be sufficient interest felt, I will draft my memoranda into a second paper.

Finally, I wish to say that for the application of dilute glacial acetic acid to arrest the development, I am indebted to an article published some time back by Mr. Wilkinson, and to Mr. B. J. Edwards for the admirable formulæ for developer and intensifier.

## OUR EXPERIENCE IN TAKING DIRECT LIFE-SIZED HEADS.

BY JOHN CHAFFIN.\*

I HAVE great pleasure in responding to the invitation of the Council, by giving a description of the method by which our large direct heads were taken, which have been awarded the first prize in the Crawshay Competition. I fear, however, the description will be disappointing, as I have no secrets to impart, or anything "new" (that I am aware of) to bring before you, beyond that which is already known; still, if from our experience anything useful is suggested, we shall be more than pleased in having made the communication.

*Studio.*—I will commence with the studio, which is about 30 feet long by 14 feet wide, and 7 feet 9 inches from the floor to the eaves. The roof is of the ordinary ridge or V-shape, save that the apex is not centrally placed, the glass side covering a larger area than the opposite or opaque side, by 3 feet, through the entire length of the roof. The whole of one part of the roof and side is glazed to within 6 feet of each end. Both ends are opaque, with the exception of a narrow light, which is admitted in the roof and side, about midway between the sitter and the background. We attach some importance to this intermediate light, as we believe it gives a relief to portraits which no other plan we are acquainted with will produce. It is not more than 6 inches wide, and is easily regulated by shutters, and made to fall upon any part of the background at will, and shut off altogether if desired.

*Lighting the Sitter.*—We find that greater contrast is necessary in lighting large heads than those of the cabinet or carte size. The situation of the studio allows a north-east light to fall obliquely on the sitter; and the stronger the light the more experience is required in arranging it. A large movable folding screen, covered with dark material, will be found handy in securing the proper amount of contrast; but no reflectors whatever of any kind were used.

*Lens.*—The lens is a 6½ inch portrait-combination, by Jamin, of about 20 inches back focus, a 3-inch central stop being used.

*The Plates.*—The plates receive a preliminary coating of sheet-gelatin (instead of albumen), as recommended by Mr. Tunny.

*Coating Plate.*—To coat the plate it is balanced on the cork of a bottle or jar, and tilted gently at the corners, to allow the collodion to flow evenly over the surface. Plates of almost any size can be easily coated in this manner.

*Collodion.*—Five of the portraits were taken with collodion made by ourselves, the portrait of Lady, No. 339, being taken with Mr. Edwards' collodion, of Hackney. The formula of our collodion is as follows, viz.:—

Alcohol, pure, 825	.....	40 fluid ounces
Ether, methyl, 720	.....	40 "
Soluble paper	.....	300 grains
Cotton giving a powdery film	.....	350 "

This is mixed and well shaken many times during the day, and then allowed to settle five or six days, or longer if not sufficiently clear.

Iodizer.—Iodide of ammonium	.....	700 grains
Bromide of ammonium	.....	500 "
Bromide of calcium	.....	400 "
Alcohol, 820	.....	20 fluid ounces.

\* Read before the Photographic Society, November 10th.

It is iodized by adding 1 part of the iodizer to 4 parts of the plain collodion. The plates were sensitized in a neutral 40-grain bath, in a flat dish.

*Exposure.*—The exposure given to head No. 337 was seventy seconds; the picture was taken at eleven o'clock in the forenoon. No. 338 was taken at half-past three in the afternoon, and exposed 100 seconds. No. 339 was taken about twelve o'clock, in a dull light, with an exposure of 2 minutes.

*Developer.*—The developer is that which Mr. Edwards gives with his collodion. The negatives were not redeveloped with pyro and silver; but should a plate appear too thin for printing, it is placed in a strong light (say for half an hour), when it will generally be found to have acquired sufficient printing-density. It is then fixed in a weak solution of cyanide.

*Printing.*—The negatives were printed on double albumenized paper, manufactured by Mr. Hart, of Kingsland Green. It was floated (three minutes) on a 60-grain silver solution, and toned in a phosphate of soda and gold bath.

GERMAN CORRESPONDENCE.

BY DR. H. VOGEL.

TALBOT SENSITIZED PAPER—HEARN'S PRACTICAL PRINTER—REPRODUCING NEGATIVES—STYLISH BACKGROUNDS—CELLULAR STRUCTURE OF THE COLLODION.

PERMANENT sensitive paper has for years been an article of commerce here in Berlin. It is consumed in enormous quantities by machinists, architects, draughtsmen, &c., who copy drawings with it. It is the same process which is worked by Mr. Walker in Washington. The drawing is placed in the printing-frame, the sensitized paper on top of it, and the negative copy so obtained is not toned, but simply fixed and washed. The process is as old as photography itself, but its general practice dates from the time when Talbot here commenced to manufacture his permanent paper for the trade, for the engineers do not like to take the trouble of sensitizing their own paper. Talbot makes his paper by floating the sensitized sheets on a solution of a salt of tartaric acid. There are many formulæ for making such paper. I myself have tried several, and all with good result; but I have never obtained a paper which was as permanent as that of Talbot, for it remained in my dark room white for eight months, in spite of the influences of air and dampness. This, however, is not dependent on the formula, but also on a skilful manipulation. Talbot's paper is less suited for photographic purposes, as it tones poorly.

I see that Mr. Hearn, in his excellent work, "The Practical Printer," a book which contains an abundance of interesting matter, treats this subject also. I fully appreciate the thoroughness with which Mr. Hearn treats everything of interest for the printer. In a future edition of this beautiful book probably a new chapter will find place. I mean on reproducing negatives, for the new method of reproducing negatives is in fact a printing process, although with development. We cannot be too thankful to Mr. Obernetter for his publication of this process, which, in fact, is so easy and simple that every photographer succeeds with it after a few trials; and I feel convinced that in two years it will be practised in every atelier of any importance. The ordinary materials, dextrine, chromate of potash, and grape-sugar, can be bought almost anywhere; but of great importance is a very fine plumbago. We get ours from Nuremberg. Recently I received a sample of excellent plumbago from Mr. Bierstadt, in New York, which appears still more intense than the Nuremberg, and my first plates made with it were too dense. A few trials teach us how to use it. It is to be regretted that this method of reproducing negatives was not known earlier; for it would have saved many a valuable plate—as, for instance, my valuable Aden plates, all of which were lost.

Before the French Photographic Society Mr. Geymet claims that he has practised this process eighteen months earlier than Mr. Obernetter. This is in so far wrong, as Obernetter made "Lichtdruck prints" as far back as 1870 from negatives reproduced in this manner. The dust process is not new; neither Obernetter nor Geymet have invented it; but the main point is, that Woodbury, who worked after the formula published by Geymet, did not succeed, while perfectly successful with Obernetter's method.

Bierstadt, in New York, has sent to me a formula which differs somewhat from Obernetter's. I tried it, and it worked splendidly. It is as follows:—

Dextrine	...	...	...	4 grammes
Grape-sugar	...	...	...	4 "
Bichromate of potash	...	...	2½	"
Water	...	...	100	"

You will notice that no glycerine is used with this formula, which is surprising, as I thought it indispensable for the dry climate of New York. Further experiments must explain the action of the glycerine.

All the world complains about the difficulty of getting an artistic background. Plenty of backgrounds can be bought, but they are all too stylish, and rather suited to spoil the picture than to embellish it. Formerly the photographers got their backgrounds painted by scene-painters, but these were often very picturesque, and not always useful for photographic purposes, either too light or too dark in tone—in short, something was always wanting. Lœscher and Petsch paint their own backgrounds, and possess in Mr. Hartman an artist who thoroughly understands his business. All the other photographers are in a bad fix, as lately the scene-painters refused to work for them. In many instances backgrounds have been returned as useless, and this has induced them to refuse further orders.

Brothers Tœschler, in Switzerland, have now adopted a new method of making backgrounds. They place the figure in front of a monotonous background, and paint the accessories, which appear to them suitable, on the negative. They coat the back of the negative with a dull varnish, and make on it the drawing with lead-pencil. It consists of very simple objects. The effect is surprising, but it requires, of course, an artist.

In view of this absence of artistically beautiful backgrounds, it is advisable to use in their place wall-paper. Beautiful wall-papers are at present in the market, particularly cloth-paper with panel and frieze. Their artistic effect is very striking, and their photographic action is good. Colours which appear too light or too dark may readily be modified by either painting them with yellow ochre or with white. Our photographers here have employed these papers already very successfully.

We hear frequent complaints that the collodion of commerce shows so-called cellular structure. The plates look after development as if covered with a fine network, which under certain conditions makes the whole plate useless. I have examined a great many samples, and found this fault almost in every one of them. Very often it is not to be noticed with the naked eye, but with a magnifier of about one inch focus it is easily noticed. American collodions do not show this fault as much as the European ones. It manifests itself particularly in summer-time, and with fresh collodion more frequently than with an old one.

I have noticed it often, and in the highest degree with newly iodized collodion. Four weeks later not a trace of it could be noticed, and the plates were perfectly smooth. The probable reason is that collodion is now generally prepared at a lower temperature than formerly; this makes a thicker collodion, more sensitive, but also less smooth. Mr. Quidde remarks that this cellular structure is more frequent when the plates are warmer than the collodion which is poured on. He keeps his plates in summer-time in a very cool place. Mr. Primm states that with careful manipulation in pouring on the collodion this evil may be avoided. Certain it is that diluting the collodion will avoid it.—*Philadelphia Photographer.*

## SUPPLEMENTARY LIGHT FOR REDUCING CAMERA EXPOSURES.

THE value of diffused light as an accelerator should be one of the things most easily tested, and the precise advantage gained determined beyond the possibility of further question. Curiously enough, it remains the subject of most conflicting opinions and contradictory statements. If it be a fact that by submitting the sensitive plate to a regulated amount of light before or after exposing it to the image of the sitter, the usual time of sitting may be reduced one-half—and this is the claim made by Mr. Fry as the result of experience—it is a fact of the most vital importance, which every portrait photographer should hail as an inestimable boon, especially during the dull, inert light of an English winter.

But, oddly enough, despite the definitely stated experiences of many, the use of supplemental light is by no means common. Some absolutely deny that anything is gained: they have tried carefully, and failed completely; and they are satisfied that the notion is a delusion. Others have tried with some advantage, but have found uncertainty and risk of fog; and they have not thought the plan worth attempting to adopt in general practice. And a great many more have not tried the process at all. The interesting question for consideration is, however, what is the cause of the negative results, or the positively objectionable results, obtained by some experimentalists? In many cases there is no doubt that this may be due to a careless and perfunctory mode of trying the experiment. Mr. Fry remarked that he could trace a large number of failures to the fact that the experimentalists had not followed instructions, but adopted some plan of their own which really did not carry out the principles involved. But the experience related by Mr. Sawyer did not admit of this solution. Mr. Sawyer stated that they had attempted to avail themselves of the alleged advantages of pre-lighting at the works of the Autotype Company, where they were largely engaged in reproducing large paintings. They had tried the plan carefully, giving the sensitive plate various degrees of pre-exposure from five to thirty seconds, but without any advantage whatever. The moment sufficient pre-exposure had been given to produce any appreciable action, the result was a certain degree of general fog, which increased in the ratio of the increased exposure. Experience of this kind, in opposition to the successful results of equally careful experiment, is very perplexing; but it may possibly be explained. We may remark, however, in passing, that the most respectable negative evidence is of comparatively little weight com-

pared with positive evidence. One well-authenticated case, in which the use of supplementary light sensibly reduced the exposure, would possess more value as evidence than a dozen cases in which it failed to do so. The former proves a possibility; the latter may simply prove that some condition of success was wanting, not that pre-lighting was really useless. But the case Mr. Sawyer stated, we think admits of a possible explanation, not antagonistic to the theory that diffused light is valuable in shortening exposures. In copying paintings, the exposure is, from various causes, necessarily much longer than would be required for producing a photograph, as vivid and full of relief and contrast, from nature. As a rule, the most brilliant painting is much lower in tone than nature, and this fact, together with the non-actinic quality of many of the colours, renders the exposure very long. Now during this long exposure there is a practical exposure of the sensitive plate to diffused light, as well as to the light forming the image. Every portion of the canvas is reflecting surface light into the lens, as well as the copy of the picture itself, during the whole time of the exposure, and one of the difficulties of picture copying arises from the fact that when the painting is in very low tone, or in very non-actinic colours, involving very long exposure, a general fog, producing flatness, dimness, and general want of contrast, relief, and vigour, often ensues. This being so, it is easy to understand that any additional exposure to diffused light would produce sensible fog rather than reduce the exposure. Mr. Fry's statement of his experience, when giving some idea of the right amount of exposure to diffused light, was to the effect that when any appearance of fog was produced the exposure was too long. In the case of the paintings it is manifest that the additional diffused light, beyond that reflected from the surface generally, was in excess, seeing that it produced fog.

The winter weather, and dark days, and comparative leisure which are before portraitists for a few months, afford ample opportunity for testing the question. Various modes of applying the diffused light are efficient; but perhaps none are better than the plan of using a cap for the lens with a disc of opal glass. This is the method which has been found so efficient by some distinguished portraitists in Paris, and which Mr. Fry has found so satisfactory. In the early days of the art the Daguerreotypist, when about to take a baby, or in any case where a short sitting was necessary, and the light dull, simply held his sensitive plate to diffused light for a second before placing it in the camera. We have adopted this plan with Daguerreotype plates scores of times with advantage. A curious experience was related to us a few days ago by one of the most eminent portraitists in the kingdom, which illustrated another mode of applying diffused light. Having occasion to use a new dark-room, and abandon that in which he had worked for some years, he was puzzled to notice a sudden and inexplicable change in the character of his pictures. Giving the usual exposure which his judgment dictated, the negatives were all under-exposed, and the general character quite different to those he had hitherto produced. They were hard, full of contrast, singularly clean in the shadows, but lacking in harmony, and a considerably increased exposure was necessary to acquire the old character in his negatives. The explanation subsequently discovered was, that the new dark room was made, *secundem artem*, perfectly dark, with the exception of the small portion of light through perfectly non-actinic glass; whilst the old room, somewhat patched up and make-shift, had admitted a sensible portion of actinic light. Another method of applying the supplementary light was patented in this country by Mr. Gage, an American photographer, something like half-a-dozen years ago. He gave the plate a preliminary exposure to diffused light as reflected from a dark, dull surface, like that of black cloth, a method we tried with unquestionable advan-

tage. Lining the camera with white paper, which has been proposed, and advantageously tried by some, seems to have the disadvantage of not being under control: whilst exposure through ground or opal glass, or exposure to a surface reflecting a small amount of diffused light—such as a dark background, for instance—gives the operator opportunity for exercising judgment. The various methods are, however, easily tried. A camera with repeating back, such as is now commonly used for card portraiture, permits two negatives with the same lens on the same plate, to be taken in rapid succession; and if a good negative be obtained in twenty, or even thirty seconds, and supplementary exposure, which would require forty seconds without the supplementary aid, there can be little doubt of the value of such a power, especially in large portraiture, where lenses of long focus must be used.

The very important question asked by Mr. Hughes at the South London Technical Meeting, whether the reduced exposure was obtained at a sacrifice of any kind in excellence or brilliancy, was promptly answered by Mr. Fry's statement that there was no loss whatever of any good quality—in fact, no difference perceptible in the character of the negative.\* Mr. Blanchard, who emphatically affirmed the value of the supplemental exposure—especially in producing large pictures in dull light—was somewhat more cautious. He affirmed that an absolutely good quality was gained. "Call it fog, or whatever you like; it is in reality harmony, the most important quality to gain—the quality in which photographs are most frequently lacking; and this harmony is secured, which would otherwise be only obtainable by very long exposure, if in dull weather at all." If the theory we have ventured to maintain before be correct, reduction of exposure without loss of any kind is possible. In our view, the preliminary exposure to light, when rightly timed, serves to initiate a change in the sensitive film insufficient to produce reduction without further action of light, but which, when duly carried on by the light from the image, materially abridges the required amount of action from the image. In short, that here, as in mechanics, that it requires a stronger force to initiate a movement, to overcome the *vis inertia* of a body, than to sustain or continue that movement when once begun. In referring to the theory of the matter, we are reminded of a question put to us a few days ago as to whether supplementary lighting—using the word in its most confined sense, as indicating diffused light following camera exposure—were as efficient as pre-lighting. At first glance we were disposed to think not; but on further thought there appears to be no reason to doubt it. In the first case, diffused light initiates an action which would not result in a deposit on applying the developer if the light of the image did not continue the action. In the second place, the diffused light carries on the action already set up by the light of the image, without being sufficient to initiate an action where the luminous image has not already commenced it. A special advantage is gained at times in being able to apply the supplemental light where pre-lighting has not been attempted. Where a child, an animal, or any sitter is seen to move before exposure is completed, the lens may be closed; and by a judicious supplementary exposure to diffused light a printing negative obtained from a plate which would have been otherwise absolutely useless. We repeat that the experiment is easily tried, and is certainly worth trying; but it should be tried with sufficient precision and care, if the results are to be trustworthy.

**BRILLIANT NEGATIVES AND FINE PRINTS.**

UNDER this title Dr. Liesegang has just issued a little pamphlet which, although referring especially to the strontium and lithium collodions prepared by his firm at

Elberfeld, contains much useful knowledge to photographers in general. The whole of the operations connected with the practice of photography are clearly described, and the formulæ cited which in his experience are the best.

He recommends the employment of two developers, the one for soft and the other for brilliant negatives.

For brilliant negatives:—

Water	...	...	...	100	parts
Sulphate of iron	...	...	...	5	"
Lump sugar	...	...	...	5	"
Glacial acetic acid	...	...	...	3	"
Spirits of wine	...	...	...	5	"

For soft negatives:—

Water	...	...	...	100	parts
Sulphate of iron	...	...	...	3	"
Sulphate of copper	...	...	...	3	"
Glacial acetic acid	...	...	...	5	"
Spirits of wine	...	...	...	5	"

Both of these solutions require keeping a day or two before they can be employed with advantage. Dr. Liesegang advises the operator never to pour more developer upon the plate than it can hold. When the plate is moved gently to and fro, as little as possible of the developer should be allowed to fall; for the more developer added, the weaker will be the negative. The developer remains so long upon the plate till all detail in the shadows has been brought out; it must be poured off, however, before the deepest shadows become fogged.

The cleaning of plates before being collodionized is a subject that receives attention, and any plates which after a thorough washing show patches, when breathed upon, are recommended to be immersed in a mixture of

Water	...	...	...	6	parts
Sulphuric acid	...	...	...	1	part
Bichromate of potash	...	...	...	1	"

Old plates should be rubbed with acetic acid and alcohol to which a little tincture of iodine has been added; a rag or bit of filter paper suffices to apply the mixture.

The collodion upon the plate should set perfectly before it is introduced into the dipping bath. If put in too soon, the film becomes dirty and dark, and unequal patches are formed, which are seen by transmitted light as soon as the plate comes out of the bath. If the collodion is sufficiently set, these defects are never seen. In cold weather the bath, as also the developer, may be warmed with advantage.

Summing up the defects that occur in the wet process, Dr. Liesegang says that fog may arise from badly cleaned plates, from an impure or neutral silver bath, from light finding its way into the dark room or camera, and from under-exposure and over-development. Patches arise mostly from the dark slide being wet and dirty, and from the employment of too fresh collodion.

As regards printing, Dr. Liesegang advocates a stronger bath, and longer treatment of the paper upon it in the case of a very brilliant and highly albumenized material. A durable sensitive paper may be obtained by preparing a sensitizing bath made up of two solutions:—

A.—Nitrate of silver	...	...	...	15	grammes
Water	...	...	...	100	"
B.—Citrate of soda	...	...	...	5	grammes
Water	...	...	...	100	"

By mixing together these two solutions, a thick white precipitate is formed, which disappears on the gradual addition of pure nitric acid, which is stirred into the mixture. Care must be taken not to add too much acid, so that there may not be an excess of it.

The toning and fixing processes are also treated of in full by Dr. Liesegang in his handy little volume.

\* See letter from Mr. Slingsby on another page.

### THE USE OF SCREENS IN LIGHTING SITTERS.

UNDER the heading, "A New System of Lighting," Mr. C. E. Myers gives in our Philadelphia contemporary details of his use of screens and reflectors in portraiture, remarking that he found at the recent Convention at Chicago only a few of the more intelligent familiar with the value of such adjuncts to efficient lighting. He says:—

"For simplicity it will be understood, in this connection, that the subject to be lighted is a human head or bust, and the light as striking it from one direction only. This may be direct sunshine, or it may be a top-light, or a top and north side-light, or any other form of opening, the light being always an 'open light,' and the centre of the opening the centre of the light. The subject is placed at the point of strongest illumination of the face, and a screen is interposed between it and the opening admitting light. A yard square translucent screen thus placed softens the light. If near, the lighting is flat; if further removed, the effect is lessened, and at the distance of a few feet it is practically without effect. Its office is to soften the light, not to govern it, and for this latter purpose other appliances are necessary in connection with it or without it. Its proper position is between the subject and the point where the strongest light enters. As regarding effect, its angle is immaterial. A horizontal or a permanently inclined screen, attached to a common head-rest, so as to be adjustable for height or revolution about its standard, is the limit of effect.

"This is the beginning of the screen theory of lighting.

"If, instead of the ordinary translucent screen (recognized always as the white or blue screen), we use a semi-opaque material of some non-actinic colour, approximating to the colour of freckles, tan or skin blemishes, such as pale red or pink, light yellow or pale orange, or very light brown, the effect of the screen is immediately visible in the lessened necessity for retouching to remove skin defects, the skin having been lighted all one colour. The prolongation of exposure is much less than might be expected before trial, for the darker and lighter parts each get their proper share in gradation, instead of the whiter parts stealing the free silver, as is ordinarily the case while developing. The softening effect is also visible, as with the white screen, but less in degree, requiring us to place it further from the sitter and out of the camera's view, the exposure being, consequently, still less prolonged. This peculiarity marks the distinctive and opposite characteristics of the translucent and semi-opaque screens.

"With the first, softness is produced, even to the extent of flatness, by putting it close to the subject. With the second the shadows are stronger if the screen is placed very close, and it has to be removed to soften effects, the proper distance being a matter of experiment; and when tried it is found that, unlike the white screen, the angle or position has a marked effect on the particular lighting of the subject, rendering perfection of adjustment absolutely essential for the desirable effect. These experiments are best verified with the common hand-screen, and it will be found that the usual conglomeration of curtains, shutters, and sliding-screens, over the top-light, may be entirely dispensed with for the mere lighting of the sitter, thus saving expense, time in adjustment, and shortening the exposure still more.

"With a universally adjustable opaque screen the lighting effect is more marked, and the control of the light is as complete as it is possible to contrive with any form of curtains. Try it on a large doll with a palm-leaf fan.

"If the coloured screen is used it will be found effective in lessening retouching only on that side of the face exposed to it, leaving the darker side of the face woefully in contrast. The remedy is a reflector. A plain white reflector improves matters by lighting the darker side, but a white patch in the near eye is nearly always an accompani-

ment. If a coloured reflector is used this side of the face is manifestly improved as regards retouching, but remains too dark for pleasant contrast or satisfactory gradation. The remedy is to concave the surface of the reflector exposed to the sitter. The light is then concentrated to such an extent as to occasionally seem to reverse the former lighting of the face. This excessive effect is remedied by moving the reflector further away. The patch in the eye disappears when the concave reflector is swung so as to light only that part of the face below and back of the eye, and the darker parts of the hair and neck, leaving the direct light to illumine the eyes. The effect is always less on the plate than it appears to the artist's eyes, as the light is coloured, and the reflection of a coloured concave surface in the eyes, even when fully fronting it, is so insignificant as to be practically ineffective. If this reflector is not sustained and wielded by the hand it must be attached to some support permitting complete adjustment, as perfect accuracy of position is more decidedly essential in the reflector than in the screen itself.

"Since reliable lighting appliances have assumed the importance they have, and in view of the almost entire lack of information on this subject, I have thought it expedient to give these concise results of miscellaneous and detailed experimental experience. I will add here that I work a north light covered with clear glass, open all the year round."

### ON THE ESTABLISHMENT OF A BRITISH PHOTOGRAPHIC CONGRESS.

BY JABEZ HUGHES.\*

WHEREVER civilised men are gathered they seem to feel it a duty, as they certainly find it a pleasure, to form societies for the cultivation of whatever art or science they have an inclination for. Not content with merely instructing each other, they, through their journals, acquaint the world with what they are doing and what they have accomplished. Thus knowledge is cultivated, established, and diffused.

A still further development of this mutual form of cultivation has taken place in our times by the establishment of annual gatherings of all those who have some common object of study. These annual meetings in no way dispense with the need of local societies; they are supplementary to them. They not only supply the opportunity of the leading men of the various local societies meeting together, but they permit those also to assemble who are removed from the local centres, and who otherwise are without means of personally meeting with their fellow-workers. These yearly meetings become, in fact, annual parliaments for the promotion of some definite purpose. One of the advantages—and, perhaps, one of the greatest advantages—thus realised is the opportunity afforded to men of meeting together and strengthening their cause, by adding to it the closer bond of personal friendship. As the custom is now so generally established of having a period of relaxation during the autumn, that period is properly utilised to hold these meetings; thus the holiday is made capable of intenser enjoyment.

A "congress"—the name often given to these yearly gatherings—may be defined to be a large society composed of members living so remote from each other that they can assemble but once in the year. As a matter of convenience, as well as to give variety, the place of these meetings is usually changed each year; the additional duties and pleasures of host and guests are thus annually varied. The British Association for the Advancement of Science is the most marked example of these comprehensive peripatetic meetings. This Association, by its division into special sections, was apparently intended to embrace all the sciences and some of the arts. Fresh organisations, on a similar basis, have, however, been formed for the cultivation of

\* Read before the South London Photographic Society.

social, medical, archæological, and other sciences, as well as for other purposes; and the best proof that there is a need for such societies is that the number of them is increasing.

Seeing, then, that persons following other pursuits find the advantage of such annual meetings, I raise the question: Are they not equally applicable to photography and to photographers? To consider whether there is room for such an organisation is the purpose of this paper, and in addressing you I address also the great body of photographers, amateur and professional, scattered throughout the country.

No argument is needed to show the desirability of photographers meeting together to discuss any and all questions appertaining to the art. At present no means exist by which photographers in their collective capacity can meet and take counsel together. The best that can now be done is meeting together in the local societies and communicating with each other through the photographic journals. But these limited means seem inadequate to represent the collective photography of the country. The few existing societies are widely apart, whereas photographers are in every town and in several large villages, to say nothing of the many skilled amateurs who reside in remote and out-of-the-way places. At least once a year an opportunity should be afforded for all who are interested in the art, wherever they may reside, to assemble together, and there to discuss in a broad and comprehensive spirit any topics of especial moment.

We are bound to recognise the fact that, year by year, photography is rapidly becoming a matter of great importance. It is no longer a scientific curiosity, an agreeable pastime, a fascinating hobby. To some it will always remain of this character, and long may they enjoy their interesting pleasure; but to the bulk who practise the art it is a serious affair. With them it is their only way of earning a livelihood, of rearing their families, and of providing for declining years. The future development of photography will be materially modified by its changed aspect. When it was in the hands of the scientific man and the amateur, all fresh knowledge was freely given forth without money and without price: but now that vast stakes are invested in its commercial applications, every improvement has a definite financial value, and is capable of being turned into money.

This is a delicate subject to touch on, but I think it explains why professional photographers are and will be more chary in unbosoming themselves than amateurs. I think, also, that here will be found the explanation why photographic societies cannot exist in small towns. It is not so much in the smaller number who practise the art as it is in the trade rivalry and jealousy that prevent them associating and exchanging ideas. A clever man will not willingly educate his less skilful neighbour when the latter may use the knowledge against him by underselling or taking away custom; but the same man will willingly impart knowledge to another who lives a hundred miles apart. Anything, therefore, that can be done to relieve professional photographers from this pressure will produce benefit. I think that many will more willingly impart their knowledge to a great gathering than to a local society. There is something specially sympathetic in the meeting of those who come from distant places to see each other; the renewed personal contact, the flash of the eye, the tone of the voice, the grasp of the hand, stimulate men to thoughts that never otherwise would have found utterance. Therefore it is good for men to assemble together.

As such meetings always partake of the holiday character, people must assemble more or less in a jubilant condition, and meeting with others having the same objects in life, they cannot but benefit by the welcome they give each other. Meeting under such conditions, relieved from the worry of sitters and the smell of chemicals, men must benefit when they see those they read and hear about, and whose works they admire, even though no well of information

burst forth or no fresh fountain be discovered. If increased strength be gained by attending ordinary photographic meetings when the body is weary and the mind full of care, how much more renewed vitality may not be acquired by new scenes, fresh faces, and the renewal of warm friendship! I dwell more particularly on these social advantages, for if nothing else be gained, these are certain to be forthcoming. I am assured by those who attend similar meetings that these enjoyments are by no means to be despised.

But, granting for argument's sake that an annual photographic congress is desirable and practicable, is there any need to have a special organisation for the purpose? Cannot some existing means be utilized to provide photographers an annual gathering? As papers on photography are occasionally read at one of the sections of the British Association, could not that be adopted as a centre of union? I have thought of this, and before photography was so well established perhaps it might have been done; but it could not be accomplished now. Somehow photography, although the child of science, has never obtained a good foothold at the British Association, and, especially since the death of the lamented M. Claudet, each year it seems to have less. Scientific men, as a rule, do not understand photography. Its broad and general principles, of course, they grasp; but the minute details of its reduction to practice and application to commerce they properly ignore. But it is exactly these details and applications which are most interesting and valuable to photographers. Photography seems to have a little world of its own; and from what I know of the working of the sections I do not think any satisfactory nucleus could there be found. I think I should be supported in this view by the experience of those few photographers who are in the habit of attending the meetings.

That there is desire and a willingness for photographers to assemble annually, and even to travel a considerable distance to do so, is evidenced by the numbers who come from different parts of the kingdom to be present at the opening *soirees* of the parent London Society, and who attend at the technical meetings of this Society. It has been mooted more than once that the sphere of action of the parent Society of London might be enlarged so that, by an arrangement of annual peripatetic meetings, some such scheme as I am alluding to might be accomplished. I have my doubts of this. Although that Society has changed its name, I think it can never be other than a London Society; besides, it has sufficient scope in attending to its own business and duties.

I do not think that any local society can be so extended as to absorb the photographers who are scattered through the country. I think such an organisation as I am alluding to, while it might be composed of the men belonging to any of the societies, or to none of them, yet should be in harmony with all. It should trench on none of the local centres, but might be the means of causing additions of members and of information to all. It would probably hold its meetings at times and under conditions different to them, and its chief purpose should be the bringing within the fold a large number who now, from isolation and other causes, are debarred from personal photographic union.

It forms no part of my present purpose to suggest the exact business of this congress, nor how long it should be held—whether papers should be read, apparatus or appliances shown, processes worked, a technical demonstration made, or an exhibition held; but I certainly think its purpose would not be gained if a field-day or excursion were omitted, and, where the circumstances were favourable, I think a *soiree* should be held, where the ladies could participate in the enjoyment. If the idea be worth carrying out, all these details are the work of the managing committee. As to the good which would result from these annual reunions I am not willing to prognosticate.

I am not so sanguine as to suppose that we should be

immediately able to make our negatives much better or our prints more permanent—that we should be able to obtain better prices for our work, or raise the status of our profession; but I see no reason why any or all these objects might not be aided, and other advantages be obtained.

Our American brethren have set us the example in forming such an organization. In addition to their local photographic societies they have established a National Photographic Convention, and from the enthusiasm that prevails at their meetings the idea is eminently successful with them. We labour under fewer difficulties than they do; for, from their immense continent, many have to travel enormous distances to attend—even thousand of miles—and yet they seem so gratified with their results that, in separating, it is only with a determination to make their next meeting more agreeable and useful.

As I have already intimated, I bring the general subject for you and others to discuss. I feel that our present societies do not embrace all the photographic talent that exists. I think there are many good and true men that are lost to us, and which our present machinery cannot include. I feel also that something should be done to create a feeling of pride among ourselves that we follow an honourable profession and practise a beautiful art. I think that we have so many good and worthy men attached to the craft, that it is a pity they do not know each other better; and I humbly suggest some such scheme as this as an additional means of bringing them together, so that they may know and esteem each other. We hear and read of the pleasant time some of the societies enjoy when they have a field-day out, and I ask why cannot there be a general field-day? Why cannot we have on a larger scale a holiday in the woods? Suppose we suspend a meeting or two in the winter, and hold them in summer—in daylight instead of night; not in a dingy, yellow-lighted dark-room, but under the canopy of heaven. All this, and more, may be accomplished at a British Photographic Congress.

I have purposely abstained from suggesting how such a scheme should be started. I submit the broad idea only for general consideration. But I must remark that to be successful it should be so comprehensive as to embrace all, and not be the emanation of any special section. It must not be appropriated by any one society, nor be the rival of any. Whether independent men from all parts of the country should mature the plan, or delegates from the metropolitan and provincial societies, together with those who belong to no society, should unitedly bring it about, I leave for future consideration. I am inclined, however, to this latter method, as there are obvious advantages in meeting in the great centres where societies already exist.

Trusting that I have said enough to interest you, I leave the subject, hoping that you and others may so discuss it that profit and pleasure may be the result.

### Correspondence.

#### KENNETT'S PELLICLE.

DEAR SIR,—The experience of a "Portrait Painter," recorded in last week's NEWS, with regard to the extraordinary rapidity of the pellicle, exactly coincides with what I have stated on more than one occasion regarding my own experience and that of several of my friends. The excellent results have been many times exhibited and admired, yet the inventor is out of pocket by his discovery. The fault, is, however, I think, in a great measure due to Mr. Kennett himself, and as it is perhaps not yet too late to apply a remedy, I venture to propose one that may prove effectual. Let him raise the price of his pellicle to at least four times its present rate. It will show that he knows how to value his own discovery, and may lead others to do likewise. Photographers are very like the rest of the world—apt to be deceived by noisy pretenders, while they neglect

real merit, especially if it have the added sin of modesty. "Thy truth shall be thy dower," as poor old Lear expresses the amiable sentiment. Let Mr. Kennett try this one more experiment, and tell us the result.—Yours truly,

R. W. ALDRIDGE.

#### THE PHOTOGRAPHIC SOCIETY.

SIR,—Like your correspondent of last week, "L. N.," I have attended many years the meetings of the Photographic Society—in fact, ever since the time of Scott Archer. But I differ utterly from him in his opinion of the last meeting, and think the conduct of the President most admirable. It was quite a revival at Conduit Street to see a good spirited discussion all over the room encouraged and stimulated by a genial chairman. I fear "L. N." has a good deal of disappointment in store, for he may rely upon it a genuine revival has begun; and I trust the tone and manner of the last meeting may be the key-note for the others of the session, now that the long repression of discussion is so happily ended.—Respectfully,

SAMUEL FRY.

#### REPRODUCING NEGATIVES.—THE PLUMBAGO POWDER PROCESS.

SIR,—When I was at the Exhibition of Photographs a fortnight ago, I saw samples of reproduced negatives by the plumbago process. I at once saw the advantage of that method; and I again saw other samples at the Technical Exhibition at the Cambridge Hall, Newmarket Street, and I determined to try my hand at the process, with what result you will judge by the three specimens enclosed.

No. 1 was exposed for three minutes in the sun. No. 2 the same time, but the sky was very much more worked upon with the plumbago, which you will see has almost made it print white paper. No. 3 was exposed twenty-five minutes in a good light without sun, which you will see is much harder. This will show that almost any kind of negative may be made by regulating the amount of plumbago. I find that it is best to use rather a long soft camel-hair brush to apply the plumbago with, and go over the plate many times to get the best and softest negative; but if the sky is wanted a little more dense, then a shorter and thicker brush is best, so long as it does not scratch.

The plates were first coated with a thick plain collodion, and placed in water when well set; as soon as greasiness had gone by washing, the plate was taken out and drained, and then the sensitive mixture poured on same as collodion, and dried by the fire and placed on the negative in the printing-frame. The sensitive solution is the same that Mr. J. Werge gives, and I think it has been given in the NEWS; it is as follows:—

Dextrine ... ..	1 drachm
Sugar candy ... ..	1 "
Bichromate of ammonia ...	$\frac{1}{2}$ "
Water ... ..	5 ounces

The water is best slightly warm. The other part of the process has been given before in the NEWS, so that I need not go over it again. The films of these specimens were easily stripped from the glass and transferred to one coated with a thin solution of gelatine containing a grain or two of chrome-alum. Should anyone wish to see the prints, perhaps you will show them.—I am, sir, yours truly,

Scarborough November 11th.

GEO. WILLIS.

[The prints with which our correspondent favours us admirably illustrate his remarks, and show at once the excellence and simplicity of a process which can yield such results on the first trial after reading the description.—Ed.]

#### SUPPLEMENTAL LIGHTING.

DEAR SIR,—I send you the enclosed photograph showing the value of a preliminary exposure. The group was taken on the afternoon of the 10th inst., at 3.35 p.m. An exposure of two seconds through a plate of opal glass was first

given, the actual time of sitting being thirteen seconds, with full aperture No. 3B, all blinds in studio being open. Previous to this I had been giving twenty-five seconds, full aperture No. 2B, for cartes, with blinds partially down. You will agree with me that my chance of securing a picture without the opal was a very small one.—Yours very truly,

R. SLINGSBY.

[The example enclosed is a cabinet group of two children, admirably arranged, capital in expression, and most excellent as photography. These who know the unquestionably high quality of Mr. Slingsby's work will understand how good the picture is that satisfies him. A more satisfactory illustration of the value of pre-lighting could not well be desired.—Ed.]

## Proceedings of Societies.

### AMATEUR PHOTOGRAPHIC ASSOCIATION.

A Council Meeting of the above Society was held the 11th inst., at 12, York Place, Portman Square, T. SOPWITH, Esq., M.A., F.R.S., in the chair. The minutes of the last meeting having been read and confirmed, the following members were elected:—Heury V. D'Esterré, Allan H. Steuning, W. Horsman Kirby, G. Moore, Thomas Hutcheson, and A. L. Steavenson, Esqrs.

The SECRETARY then laid before the meeting the following prizes, which had been awarded at the last meeting:—First Prize—F. Beasley, Esq., a large silver goblet; W. S. Hobson, Esq., a silver goblet; J. H. Ravenshaw, Esq., a silver goblet; Col. Rooke, an oil painting in gilt frame by Masters; Sir J. Coghill, a large album handsomely bound in morocco; Capt. White, an oil painting by McEvoy; Major Allen, an oil painting in gilt frame by Masters; D. Knapping, Esq., a large album handsomely bound in morocco; J. McAndrew, Esq., a graphoscope; T. Brownrigg, Esq., an oil painting in gilt frame by McEvoy; G. Brewis, Esq., a large album handsomely bound in morocco; Capt. Lewis, an album handsomely bound in morocco; R. O. Milne, Esq., an album handsomely bound in morocco; Capt. Toke, an album handsomely bound in morocco; R. Murray, Esq., an album.

Certificates of Honourable Mention were awarded to W. G. Huter, Capt. Layton, J. W. Richardson, Rev. W. E. Hancock, and Mr. Hancock. A. J. MELHUIS, Hon. Sec.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual meeting of this Society was held on the 12th inst., the Rev. F. F. STATHAM, M.A., President, in the chair.

Messrs. Reid and W. F. Attwood were elected new members.

The next meeting of the Society being the annual one for the election of officers, the names of several gentlemen were put in nomination for the offices of Vice-presidents and Council. These will be balloted for at next meeting.

Mr. Jabez Hughes then read a paper "On the Establishment of a British Photographic Congress" (see page 560).

This gave rise to an interesting conversation, and a committee of representative photographers was appointed to ascertain the feelings of photographers throughout the country relative to the carrying out such a scheme as that proposed by Mr. Hughes. The Chairman, Mr. Spiller, and other gentlemen spoke in favour of the proposed movement.

It was intimated that at the next meeting, after the election of office bearers for the ensuing year, Mr. Aldridge would read a paper "On the Practice and Principles of the Great Portrait Painters." And it was further intimated that the annual dinner of the Society would be held on the 17th proximo.

The meeting then adjourned.

## Talk in the Studio.

LANTERN READINGS.—We have received from Mr. York an interesting series of details—historical, statistical, and descriptive—of various London institutions, intended as lantern readings to accompany the exhibition of his admirable series of London views. The idea is a capital one, and might with great advantage be carried out in connection with various other series of lantern slides. The mass of information Mr. York has compiled for the London series is at once interesting and valuable.

FANCY MASKS.—We have been favoured by Messrs. Rivot and Fontes with some examples of fancy masks for card pictures, the purpose of which is to print round a medallion picture a tinted margin, plain or with some neat simple design. Many of them are exceedingly excellent and effective. The texture of rough drawing-paper, or that of shagreen, is well imitated in some; a variety of fine diaper patterns are on others, all neat and in good taste. They will admirably facilitate the production of effects which give considerable finish to a portrait.

PHOTO-LITHOGRAPHIC ILLUSTRATION.—We have before us a number of the *British Architect* containing some good photographs of architectural drawings. On the cover it is stated to be "the only journal in the world containing permanent photographs in printer's ink." This is, we think, a mistake. There is an illustrated journal in Canada in which the "Leggotype process"—a method of photo-mechanical printing—is solely used; and the *Daily Graphic*, published in New York, is illustrated, we believe, by a similar process. There are, besides, in England several periodicals which contain frequent illustrations produced by photo-mechanical printing processes.

PHOTOGRAPHIC NEWS IN THE WEST.—Our new contemporary and namesake, the "Western Photographic News," has forwarded us some further numbers, full of interest, and possessing all the promise of an energetic successful enterprise. It deals much and intelligently with the business aspects of photography, especially in the wide districts to which it especially appeals.

A PHOTOGRAPHER'S RESPONSIBILITY FOR PAINTINGS ENTRUSTED TO HIM.—A curious case was tried in the Lord Mayor's Court on Wednesday, when an action was brought against the Stereoscopic Company for the value of a painting left with them to varnish. The case is reported as follows in the morning papers:—This was an action to recover the value of a portrait of the plaintiff's daughter. The defendants paid £5 into court, and pleaded that that sum was sufficient to satisfy the plaintiff's claim. Mr. Turner was counsel for the plaintiff; Mr. Kemp was for the defendants. It appeared from the evidence of the plaintiff that about twenty years ago he was living in Calcutta, and his two children, son and daughter, were at school at Surbiton. He was desirous of having their portraits in his possession, and sent instructions for them to be painted by an artist named Fisher, who, when the pictures were completed, forwarded them to India, and charged fifty guineas for the pair. Upon the plaintiff's return from India to this country he brought the portraits with him and took them to the defendants to have them freshly varnished, and have any defects made good. They agreed to undertake the matters at a cost of £1, and the plaintiff left them for that purpose. After the lapse of some considerable time the plaintiff applied for his pictures, and received an answer that the portrait of his daughter could not be found. The plaintiff now sought to recover £75, viz., £25 the sum he had paid to the artist, and £50 compensation for the loss of his daughter's portrait, which, he contended, it was impossible to replace, in consequence of its having been painted so long ago, and that its loss had deteriorated the value of the companion picture. For the defence it was admitted that the pictures had been delivered to the defendants under the circumstances detailed by the plaintiff, and that the portrait of the daughter had been lost. They were given to a man in their employ to carry out the plaintiff's instructions. The man was suddenly taken ill whilst he had them in his possession. His landlord distrained for rent, and amongst other things sold the two pictures in question. The man had subsequently died, and the picture of the plaintiff's son was afterwards found by the defendants, purchased by them for £1, and returned to the plaintiff, and they offered to paint a portrait of the daughter at her present age. The plaintiff had refused their offer, and the defendants considered that the sum of £5 was the outside value of a picture similar to the lost one. Mr. Turner, on behalf of the plaintiff, admitted that an offer had been made to the plaintiff by the defendants to colour a photograph of the plaintiff's daughter if sent to them; but he contended that that was not a sufficient compensation to him for the loss of the portrait of his daughter, taken many years ago, and to which he attached great value. Mr. Kemp contended that the value of a lost picture was what it would have fetched if offered for sale, and submitted that the amount paid into court was sufficient under the circumstances. The Jury ultimately returned a verdict for the plaintiff—damages

£25. Subsequently, upon the application of Mr. Kemp on behalf of the defendants, the Common Serjeant granted a rule nisi, calling upon the plaintiff to show cause why the verdict should not be set aside and a new trial granted on the ground that the damages were excessive.

**A SECRET EMULSION PROCESS.**—Some months ago we referred to a circular received from Japan, in which the writer, H. Hammonstede, announced a new process without silver bath, with bromide or uranium, and more sensitive than the wet process, a couple of very fine prints being sent in attestation of the excellence of the results. We learn from the *Photographic Times* that Mr. Hammonstede has arrived in New York, and is offering his emulsion process to the profession if one hundred subscribers at £5 each will combine to purchase. The Photographic Section of the American Institute have appointed a committee to investigate and report with a view to recommending the purchase if the report be favourable.

**MARRIAGE.**—It will interest our readers to know that on the 12th inst. Marie, the only daughter of Mr. England, was married to Frank W. Carpenter, only son of Dr. J. E. Carpenter, a gentleman whose songs are sung wherever the English language is spoken.

**To Correspondents.**

**ONE TROUBLED.**—The opaque, comet-like markings, with transparent nuclei, in your negative, most probably proceed from turbidity in the collodion. Floating particles of some insoluble substance, setting up increased reduction in the immediate neighbourhood, and so causing opaque streaks, the particle itself being dissolved and removed in the fixing and washing, and so leaving a transparent spot in the middle of the head or nucleus of the comet. It is probable that allowing the collodion to rest and subside for a day, subsequently decanting it, not too close, will remove the trouble.

**G. W. R.**—We regret that we cannot give you information as to the facilities for obtaining photographic goods in Queensland. Stock houses will doubtless exist there to supply the wants of photographers, but we are not familiar with them. In any case it will be wise to take a stock for immediate use with you. You will doubtless obtain information as to fresh supplies when you have been there a short time. You can receive the NEWS by post regularly; we send to various subscribers. Our Publishers will give you full particulars. We believe that prepayment of 17s. 8d. will secure the NEWS, delivered by post in Queensland, for twelve months.

**J. B. (Bombay).**—There is no book published on the subject of retouching; but there have been many carefully detailed articles in the NEWS and YEAR-BOOKS on the subject, giving all the information that can be given in writing. The only additional aid would consist in personal instruction, which, of course, you cannot readily obtain in India. You will find a great number of articles on the subject in our last half-dozen volumes, and in that for 1869 some especially detailed practical instructions; and in the YEAR-BOOKS for 1869 and 1870 you will find similar articles.

**H. P. SWAINE.**—The stain in the print is doubtless the result of hypo, and suggests that insufficient washing was the cause of the film splitting. We fear that you would risk losing the film altogether in any attempt to remove the varnish, and refix. We do not think it probable that the negatives will fade. The chief danger to which it will probably be subject is staining in any place where a trace of hypo is left from contact with the silver on sensitive paper. To avoid this risk, you may adopt two or three precautions. Take care that the sensitive paper, placed in contact with it, is not damp, or place a sheet of tracing paper between the negatives and paper so as to avoid direct contact.

**EDWIN OBORNE.**—Thanks. We have read the opinion with interest. As, however, it is purely a business document, it should appear in our business columns if published. It does not legitimately come within the scope of our literary columns.

**G. LEWIS.**—We do not know of any maker of blood albumen; it is chiefly used by dyers, we believe. In photography it has been used to some extent, we believe, in preparing albumenized paper. Its only advantage over ov-albumen is cheapness; and in the preparation of dry plates, and in use for preliminary coatings, the small quantity required would render this consideration unimportant. There is generally a slight opalescence in the albumen preservative solution, but we are unable to say whether it would be entirely absent in a solution of the dried blood albumen.

**CERBERUS.**—It is difficult to say what is the best mode of publishing a work of which we know nothing. Your best plan will be to obtain one or two estimates for the printing of a given number in a given style. You may obtain a local estimate, and you may send up the manuscript to the Printers of the PHOTOGRAPHIC NEWS, and they will give you an estimate. In any case they will undertake to publish it for you on the usual terms, details of which they will furnish you on application.

**IGNORAMUS.**—The most probable cause of the pinholes is the use of a bath overcharged with iodide. The negative suggests that the bath was turbid, charged with innumerable floating particles, which, settling on the film, cause the minute transparent spots. The plan of iodizing by pouring collodion into the bath is very undesirable, as you are uncertain of what you are adding. For instance, the collodion probably contains bromide, and thus bromide of silver is formed in the bath, and as it is not soluble, there it will remain in floating particles, causing mischief. Sometimes a similar effect to that sent will arise from the use of glass which has contained old varnished negatives which have been cleaned off with nitric acid, or some similar detergent.

**R. P.**—The set of lenses you describe belong to a magic lantern. The two larger lenses are the condensers, the smaller single lens being the enlarging lens. The plano-convex lens should be placed with its plane side next the source of light, and the double convex immediately behind the plano-convex, not quite in contact with its convex side. If you think of enlarging by artificial light, this condenser may answer pretty well; but a larger and more powerful condenser is generally used with the solar camera. The best mode of enlarging, however, does not need any condenser. It consists in obtaining from the negative a good transparency, and from the transparency an enlarged negative, simply using the white light of a northern sky. We have given full details of this method, with which you are doubtless familiar. A gelatine film will give you a very fine transparency, well suited for the purpose of producing an enlarged negative. The YEAR-BOOKS for 1871, 1872, and 1873 are in print, and may be obtained by post, price 1s. 2d. each.

**H. S.**—We do not know the address.

**CAPTAIN STRETTON.**—Thanks. We shall probably use the remarks in our YEAR-BOOK.

Several Correspondents in our next

**METEOROLOGICAL REPORT FOR OCTOBER.**

BY WILLIAM HENRY WATSON.

Observations taken at *Braystones, near Whitehaven, 36 feet above sea level.*

Date.	THERMOMETER.			BAROMETER.			Direction of Wind at 9 a.m.	
	Morning.	Noon.	Night.	Morning.	Noon.	Night.		
1	56°	60°	53°	29.54	29.50	29.41	S.	Fair and sunny.
2	53	53	52	28.98	28.96	28.96	S.W.	Showers a.m. and p.m.
3	52	54	50	28.95	29.10	29.13	W.	Rain a.m. and p.m.
4	50	52	—	29.13	29.22	—	W.	Fair, generally gloomy.
5	44	52	52	29.43	29.77	29.62	S.W.	Fair, generally gloomy.
6	54	55	52	29.42	29.29	29.02	—	Rain all day.
7	52	56	48.5	29.03	29.11	29.46	—	Showers a.m. and p.m. Windy.
8	42	57	48	29.71	29.74	29.60	E.	Fair, and generally sunny.
9	53	54	47	29.51	29.61	—	W.	Showers a.m. Gloomy all day.
10	54	58	53	29.67	—	29.72	S.W.	Rain a.m. Gloomy all day.
11	56	53	54	29.82	29.82	29.68	S.	Rain p.m. Gloomy all day.
12	56	53	56.5	29.87	29.82	29.78	—	Rain early this morning. Gloomy all day.
13	51	60	44	29.74	29.78	29.81	N.	Fair, but gloomy.
14	52	54	48	29.77	29.60	29.3	S.W.	Fair. Gloomy.
15	51	60	34	29.31	29.11	29.22	S.	Rain this afternoon. Heavy at night.
16	51	—	48	29.50	—	29.64	S.E.	Fair, clear.
17	50	57.5	34	29.42	29.47	29.60	S.	Rain a.m. Gloom all day.
18	56	56	54	29.62	—	29.51	S.	Rain a.m. and p.m. Windy.
19	52	48	50	29.51	29.68	29.90	S.S.W.	Rain and sleet a.m. and p.m.
20	51	56	56	29.90	29.89	29.82	W.	Rain a.m. and p.m.
21	51	16	49.7	29.12	29.29	29.33	—	Rain a.m. and p.m. Strong wind.
22	48	—	46	29.50	—	29.61	S.W.	Fair, generally gloomy.
23	48	50	50	29.82	29.87	29.89	—	Fair, generally sunny.
24	50	53	52	29.85	29.73	29.61	S.	Rain this evening 7.40 p.m.
25	54	54	51	29.46	29.60	29.85	S.W.	Rain a.m. Meteor.
26	49.6	54	56	29.89	29.77	29.73	S.W.	Rain all day.
27	56	—	48	29.77	29.73	29.93	—	Rain this morning.
28	47	50	49	29.98	29.96	29.95	S.S.E.	Rain this evening. Cloudy all day.
29	49	51	49	29.97	30.00	30.10	S.W.	Rain p.m. Blue haze a.m.
30	50	51	36	30.29	30.26	30.31	N.	Fair all day, generally cloudy.
31	38	50	48	30.25	30.23	30.15	N.E.	Fair all day, clear and sunny.

From the above I arrive at the following:—

	Mornings.	Noons.	Nights.
Maximum temperature	56°	60°	56.5°
Minimum ditto	38	46	36
Mean ditto	50.8	54.1	49.9
Mean ditto of whole	51.2	—	—
Number of days on which rain fell	—	—	20
Number of fair days	—	—	11
Number of fair days on which it was sunny	—	—	4
Number of fair days on which it was gloomy	—	—	7

By referring to the above observations, it will be noticed that the barometer was very unsteady, and that the weather was very unsettled during the month.

*Braystones, near Whitehaven, November 3rd.*

## The Photographic News, November 27, 1874.

## PHOTOGRAPHY IN AND OUT OF THE STUDIO.

## THE TRUTH ABOUT PHOTOGRAPHIC PORTRAITS—REPRODUCTION OF CHINESE BY PHOTOGRAPHY.

*The Truth about Photographic Portraits.*—Artemus Ward's saying, that if the leopard can't change its spots, you can do it for him, now and then comes back to you very forcibly in looking over many a photographic album. The sun cannot lie, we know, but somehow we can avail ourselves of its aid in practising a little deception. When, for instance, our friend Tittums, who stands about five feet nothing without his shoes, proudly shows us a portrait of himself that has been taken abroad, and which he vows is as far above the work of English artists as the sun is above the moon, we see that it is not so much the beauty of the work, or the grace of the pose, that has taken Tittum's fancy, but rather the general effect, which represents our friend as being rather over than under the middle height. Tittums, of course, orders a gross of the portraits at once, for he'll have no more of your rubbishing English photographs, and keeps a supply of them in his pocket-book, to be shown on every occasion. "Here, just look at this," he says, for he knows you are interested in photography; and you, who have seen the picture already a dozen times, say, as a matter of course, that, by Jove, you have never before seen anything like it. The artist has merely photographed Tittums in the presence of a suite of diminutive furniture, and hence the happy effect. Other photographers are a little more delicate in their handling of a sitter; they fear that miniature surroundings may be offensive to their model; and so they take a three-quarter sitting portrait. After focussing a while, looking at the lighting, drawing a blind here and there, giving the flower in the vase a twist, &c., they say, "I think if you were seated a little higher, it would be as well;" and a couple of big books, which happen, most fortunately, to be quite handy for the purpose, are placed on the chair, and you hoist yourself once more in position. Of course, the result is most satisfactory, for when the proof comes home, you see a tall, well-built individual leaning back in the chair in a commanding position. Cunningham, the photographer, understands human nature quite as well as portraiture, and you like your picture so much, that years after, instead of having another taken, you prefer rather to have the old one copied. There never was such a prominent feature as our friend Miss Sneezum's nose; and not only is it very long, but (so some people say) it is exceedingly crooked into the bargain. And yet we cannot see how such a false report got abroad, for Miss Sneezum's half profile portrait, which we have seen (we mean the one where she is poring over a book) represents that lady's nose as purely aquiline; and we, as a photographer of some experience, can vouch for the absence of the retouching pencil. It is all very well for gossiping friends to shake their heads dubiously, and smile as they look at the portrait, but, as we tell them briefly, and with some warmth, "Here is a direct photograph, taken by a well-known, honest photographer; now, are you going to believe it, or do you mean to tell me that the sun can reflect anything but a true shadow upon the sensitive plate? If the nose is crooked, point out the defect, for goodness sake, and don't go on maligning a poor woman without reason." Of course, they say that if the photograph had been taken from the other side, we should soon see whether the nose were crooked or not; or if there had been a little more light just in that part, the defect would have been apparent enough; but these are, of course, mere excuses. A man who will doubt the truth of a photograph, it is no good arguing with. If he had a flattering portrait of himself taken, he would be the first, no doubt, to testify to its absolute truth. Painters, we know, always represent their models in what they are pleased to term

"a happy moment," and photographers would be imbeciles indeed if they did not, in their pictures, show their sitters "at their best."

*Reproduction of Chinese by Photography.*—Photo-lithography has been aptly used, we hear, in copying Chinese characters, or writing, the difficulty involved by the intricate nature of the letters being thus very speedily got over. It appears that the large pictures from the *British Workman* have been considered especially suitable for circulation in China, and these have been printed from blocks upon wall paper with which the Chinese are to decorate their rooms. In proximity to each picture is some letter-press descriptive of the subject, the writing having been executed by a Chinese scholar with brush and pigment in the same way as native authors produce their works. Obviously the rendering of this in type would be an expensive, if not an almost impossible, undertaking in this country, but the camera solves the difficult problem in an instant. A photographic copy, moreover, has the advantage of being an absolute *fac simile* of the rounded and easy strokes of the author's brush, which are, it is said, much more inviting to the Chinese than the harder and more angular lines imprinted by metal type. It is, therefore, a singularly happy idea to have made use of photography in such a matter, for, putting on one side the expense thus saved in the production of the work, the fact that the same will have rather a native than foreign appearance to the Chinese will doubtless aid very much in its circulation throughout the country.

## ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

## § 3. PHOTOGRAPHIC EFFECTS OF THE ELECTRIC SPECTRA OF DIFFERENT METALS TAKEN IN AIR.

a. *Pure Metals.*

25. I have spent a considerable time in endeavouring to procure exact photographs of these spectra, inasmuch as the spectrum of a metal is a constant not less important than its density or its fusing point, and it frequently furnishes the means of identifying an element under circumstances in which no other method at present known is practicable.

Kirchhoff, in his elaborate and masterly researches on the constitution of the solar spectrum, has, as is well known, published, in minute detail, a map including the lines of a large number of the metals. He has, through a limited portion of the visible spectrum, laid down the position of the bright lines of certain metals coincident with particular dark lines of Fraunhofer, with a precision best appreciated by those who have followed him with most minuteness.

Much yet, however, remains to be done, even for the rays which fall within the range of the visible spectrum; and for those which are beyond the limits of ordinary vision the whole yet remains to be examined.

The lines of each spectrum are so numerous and so close together that it would be impossible, without a sacrifice of time that would scarcely be justifiable, to obtain accurate impressions of them by eye-drawing. Indeed, except by the process of photography, these lines can only be rendered visible by the aid of a fluorescent screen, under which circumstances the minute details are almost necessarily lost, even by the most careful observer.

The photographs of these spectra were obtained by an arrangement of the quartz prism and lens, identical with that already described (6), wires, plates, or irregular fragments, of the metal, according to circumstances, being supported in brass forceps connected with the secondary

wires of the induction-coil. The interval traversed by the spark was, in each case, about a quarter of an inch, and the slit was placed at a distance of half an inch from the line traversed by the spark.

The specimens of gold, silver, mercury, copper, bismuth, antimony, zinc, tellurium, thallium, and lithium employed, are believed to have been pure. The tungsten, molybdenum, chromium, and manganese, were reduced from pure oxides in crucibles lined with charcoal. The other metals were as they are furnished in commerce as pure.

26. Each metal gives its own distinctive spectrum; but it is remarkable that these differences are not obvious in the less refrangible end. The true metallic spectrum, when the sparks pass in air, is, in fact, combined with that due to atmospheric air, as has already been pointed out for the visible rays by Angström and by Alter. The photographic lines of the air-spectrum are most marked in the less refrangible portion, whilst the characteristic lines of the metals are particularly evident in the more refrangible parts. Hence, the photographs which I formerly obtained by the use of a prism of bisulphide of carbon, which transmits rays of low refrangibility only, represent, as I then correctly pointed out, lines which are chiefly atmospheric, and, consequently, they exhibit appearances which are almost identical, whatever be the metal employed.

In describing the spectra of the different metals, I shall employ the same arbitrary scale that I have hitherto used in this paper.

27. It will be observed that generally the lines, as they advance towards the more refrangible extremity, become less intense in their central portion, until, towards the extreme limit of the spectrum, the two marginal ends of the lines alone are visible, though these terminations are often rather intense. Indeed, throughout the whole length of the impressed photograph, the marginal extremities of the metallic lines leave a stronger image than their central portions, as though the incandescence of the volatilized portions of the electrodes, owing to their high radiating power, did not continue sufficiently intense during their transfer across the interval between the two electrodes to enable them to produce a continuous line. Evidently, the cause of this diminution of action operates more powerfully upon the more refrangible rays; and a higher temperature, as the experiments of other observers have abundantly proved, is necessary to the production of radiations of these high degrees of refrangibility.

Exceptions to this remark occur in the lines due to the atmosphere; this is well seen in the strong line at 110.5, which is in marked contrast to some of the metallic lines in its vicinity, particularly in the spectrum of silver, where this nitrogen-line is included between two pairs of very intense lines due to the metal itself, and which are each interrupted in the middle.

In order to abbreviate the description of the various spectra, I shall generally speak of these interrupted lines as "dots;" they, indeed, constitute the characteristic features of the different metallic spectra. These dots, if the image be exactly in focus, may usually be seen to consist of groups of very short lines closely aggregated. This is well shown in some parts of the spectrum of silver; and it is less distinctly shown in the spectrum of palladium, of copper, of antimony, and of cadmium. These spectra were taken with the screen, lens, and prism at a distance from the slit, different from those with which the other impressions were procured; some parts are consequently out of focus, but the details of other portions are shown more fully.

As might be anticipated, the spectra of the more volatile metals are the most intense—those of bismuth and antimony, of cadmium, zinc, and magnesium being especially remarkable in this respect.

A certain similarity is also observable in the spectra of allied metals, as in the case of the three metals last mentioned, also in those of iron, cobalt, and nickel, of bismuth and antimony, as well as of chromium and manganese.

It should further be observed that, in estimating the apparent length of the different spectra, considerable difficulty is frequently experienced, owing to the extremely faint impressions which the most refrangible rays commonly occasion; in some experiments, this portion of the spectrum with the same metal appears to be longer than in others made under apparently similar conditions.

The strongly marked character of the spectrum of silver, and particularly the renewal of its intensity towards the more refrangible end, rendered it very appropriate for the purpose of testing the diacetic quality of different media; and accordingly I have used it more extensively than any other metal in the experiments already detailed upon this subject.

*Thallium.*—The spectrum of thallium (for a specimen of which in a pure state I am indebted to the kindness of Mr. Crookes, its discoverer) is particularly interesting, as in its visible portion it is remarkably simple, the single intense green line being the only one visible, even when heated in the intense flame of the oxyhydrogen jet. When, however, the sparks of the secondary coil are transmitted, not only do new lines make their appearance in the visible spectrum, but also in the extra-violet portion. This character of its spectrum\* separates thallium from the metals of the alkalis. In the less refrangible portions are two strong groups of lines at about 103 and 106; three other groups occur at 116, 121, and 126 respectively, the two first less intense, the third of about the same strength as the first pair of groups. Several feebler pairs of dots follow; and the spectrum terminates with four nearly equidistant groups, commencing respectively at 136, 141, 145, and 151; the first of these groups is very strongly marked, the others are fainter, but of nearly equal intensity.

*Mercury.*—Experiments were made with this metal by soldering a platinum wire into a small glass tube which was filled with mercury and connected by means of the platinum wire with one end of the secondary wire of the coil; the other electrode consisted of a platinum wire. The spectrum obtained exhibited few lines, excepting those due to the mercurial electrode. The never-failing nitrogen line, 110.5 was evident; but there were numerous strong lines due to the mercury, the most distinct of which are those at 104, 114.5, 117.5, 119.0, 122.5, 131.0, 138, 156, 159, each of the two last forming a strong broad group of dots, the last group terminating the spectrum at 161.0.

*Magnesium.*—This is another remarkable spectrum. An intense group of lines commences at 101, at 115 a bright group of dots is seen, and between 119 and 126.5 are three remarkably intense groups of lines; the first of these comprises at least four strong lines, the second group three, and the third consists of eight or ten separate lines. This last is the most intense group that I have met with in the course of these experiments. Beyond this the spectrum is prolonged by a faint tail, which is strongest along the edges, and nearly vanishes midway between them; this tail disappears a little beyond 150.

56. It is unnecessary to give any details of experiments made with electrodes one of which consisted of one metal and the other of a different metal. Under these circumstances, the lines starting from the side corresponding to each metal are identical with those furnished by the particular metal. This mode of making the experiment is therefore frequently convenient when it is desirable to compare the spectrum of any given metal with another selected for comparison. When the difference in volatility between the two is extreme, as when platinum is opposed to mercury, it may happen that one spectrum only is seen, the lines starting from one edge of the photographic impression, and terminating at irregular distances before they reach the opposite edge.

(To be continued.)

\* Proceedings of the Royal Society, January, 1863, vol. xii., p. 407.

THE PRACTICAL PRINTER IN AMERICA.  
XIV.

FITTING VIGNETTE MASKS TO THE NEGATIVES FOR  
PRINTING.

IN fitting vignette masks to the negatives for printing, there are several things to be thought of and taken into consideration.

Due regard should be given to the background, for generally one side of it is darker than the other, especially when the lighting is after the so-called *Rembrandt*, for then it is generally the custom to have the background on the lighted side of the face darker than that on the other side, and *vice versa*, so as to give boldness and vigour to the prints from such negatives. When the background is as described, the vignette mask should not be placed so far on that side of the figure that has the darkest side of the background, because the vignette on the print will not be even, but one-sided. The vignetter should either be placed more over towards the other side, or, if you do not wish to print so far on that side (the lightest), then you can paste a piece of dark paper on the vignette mask, in such a way as to cover up a great part of the dark side, and then upon printing it face to the sunlight, the prints from such negatives will be much better, being more evenly vignetted. Oftentimes it will not in every particular answer to paste this paper on *all* of that side, because it may make the drapery print badly.

When, in lighting his subject for the shadow effect, the operator allows the light and shade to act strongly on the drapery as well as the face, then the former will print light on the side where the background prints dark, and when we place paper on the dark side of the background to prevent it from haloing out too far, we thus, in a measure, if not careful, prevent this already light side from printing so much as it ought. To remedy this, it is often necessary to cut out still further the vignette mask where the draperies are, in such a way as to permit all to print nicely on that side, without permitting the background to print out too far. Thus the outside of a vignette

Fig. 1.

mask will often have a very bad appearance as regards the shape, sometimes having the shape shown in fig. 1.

Upon looking through such a vignette mask on to the negative within, it would appear at first glance as though the vignette mask was tacked very carelessly on to the printing frame, and not until we examine the negative by holding it up and looking at it, will we discover our mistake. In changing the shape of the vignette mask, it will be found to be a difficult thing to do if it should be found to be made of wood.

Partly for this reason, and partly because many negatives require a little different vignetter, I have always used common and average thick pasteboard for vignetting the common card and imperial negatives. For larger negatives, however, I use wooden vignette blocks, and if there is anything needed to be done as described above, I make the print in the usual way, and before removing it from the frame, move the block in the direction needed, and shading the rest of the figure with a cloth, print it as required. As there are hardly ever more than two or three vignette prints to be printed from such large negatives, I prefer to do so, being less troublesome than to change the wooden block, and thus ruining them for future use; but for card and imperial negatives, when there are often

dozens to be printed, I like to have a vignette mask expressly adapted for that particular case, and then I can print right along, and finish the order without any more trouble, after having obtained the first satisfactory print.

Another advantage in using average thick pasteboard is because greater softness is imparted thereby to the halo of the vignette, if the pasteboard is raised to a proper distance from the negative.

The great disadvantage of many of the wooden vignette blocks is simply this: The opening of the under part of the blocks is not bevelled out far enough for the purpose of obtaining soft halos to the prints. When we fasten such a vignette block on to a printing frame for vignetting, the under part of the block rests on the negative, and when the opening of the block is not bevelled out far enough, the diffused light will cause a too abrupt edge to the halo. This is the reason why soft halos are so hard to obtain with wooden vignette blocks, and there are some printers who cannot obtain them, try as hard as they will. On their informing you that they never could obtain soft halos, if you were to ask the question, "What do you use in vignetting?" their reply in most cases would be, "Oh! I have had some nice vignette blocks made for me, but I cannot obtain soft halos, even if I place *two* tissue papers over the vignette.

When the block is not bevelled out far enough, the diffused light entering will cause the sharp edge to print just where the block touches the negative. This can be prevented by bevelling the block out further, and also softer. The light, as it enters through the tissue aperture, will diffuse out almost exactly as far as you are able to see under the block by applying your eye close to the vignette block and looking under. If, while looking, you see the edge of the bevelling of the block touch the negative, you can depend upon not obtaining soft halos until you remedy the defect in the blocks. When you have new vignette blocks made, test with your eye as above.

But softness to a halo cannot be obtained so nicely with a block placed upon the negative, as described above, as it can by the use of some common cardboard, with an aperture suitable to the size of the negative. In this case there is not anything to stop the diffusing of the rays of the sun, as there is in the wooden vignette block, but the light diffuses out nicely and softly, the softness depending upon the distance of the cardboard from the negative.

A few words about the distance of these vignette-masks from the negative. Never place the cardboard nearer than a third of an inch from the negative, unless in case of some faulty place that is to be avoided in vignetting the negative. If the figure is to be illuminated, so as to get rid of a defect in the background, then it is best to make a light proof of the negative, and cut close in and around the figure, being careful not to cut in too close to the neck, so as to give an ugly look to the vignette, which will always look like the cut-out, although, perhaps, it may have a softer outline (fig. 2). Place the outside of the pieces cut

Fig. 2.

on to a suitably sized piece of cardboard, and cut out the piece B, which is cast away. Place the piece A over the background of the negative, about half an inch from it, on to the raised outside of the printing frame, and after adjusting it properly, then tack it in its place. Paste a piece of tissue paper, C (French copying-paper is the best for printing purposes, being entirely free of the minute holes which

are so characteristic with the English tissue) over the cardboard, so as to permit diffused light to pass through the aperture when you place it out to print in the diffused rays of the sunlight. If, upon examining the print, the halo does not blend out soft enough, then place the cardboard away a little more from the negative, and print again. If it blends out too far, place the cardboard a little nearer to the negative.

The manner in which I obtain these different degrees of depths from the negative to the cardboard without much trouble is, if the printing masks are not raised in the making of them, to have made, and ready at hand in case of need, some pieces of basswood, of different thicknesses, which can be tacked on to the sides of the frame when needed, and the cardboard tacked on to these. Have plenty of these pieces close at hand, and in tacking them on do not use more than a couple of tacks for each piece.

If you wish to obtain a halo to a vignette that will commence close to the head to blend out and extend out to the very edges of the card, both in the background and drapery, then the distance of the cardboard from the negative should vary from a half to a full inch. The opening of the cardboard should be about the ordinary size of a vignette aperture. The greater the distance from the negative to the vignetting arrangement the smaller should the opening of the vignette be. Never use ground glass in vignetting when you desire soft halos; but tissue paper should be used, and a good quality at that.

Always be sure that the head of the negative is balanced by having plenty of the body show. In your mind's eye draw a line from each side of the face down through the body. The shoulders should always show from a third to a half of the length of the face beyond this imaginary line, and the length of the body should rarely be less than one and a quarter times the length of the head. There are many things sometimes to prevent having the above named proportion to the vignette, but always have it if possible.

The Wymouth vignette papers are undoubtedly superior to anything that has ever been devised for the purpose, and any failures in using them have no doubt arisen from the want of proper care and judgment on the part of the printer, rather than any fault in the papers, or the idea on which they are gotten up. Of course all negatives cannot be treated the same in this respect, any more than all can be printed equally well on one sample of silvered paper. A negative with a light background may print well with the vignette paper placed in contact with the glass, while one that prints a dark ground would require the paper to be separated from the glass a sufficient distance to prevent its printing a hard or abrupt edge to the vignette.

Before closing this chapter I will attempt to state what the beauty of a vignette consists in. Sometimes vignettes are meant to supply the place of shadow—as when in

Fig. 3.

photographing crosses—then we vignette in such a way as to have a shadow on one side of it (see fig. 3).

The beauty of such a vignette consists in the artistically printed shadow; and when we examine such a print we experience considerable pleasure in seeing the soft shadow caused by the cross, whereas if it were not there, or the shadow were on both sides, it would create anything but

pleasure. Then, again, the beauty of vignettes in ordinary portraits is the soft blending from quite dark, in the drapery and close to the figure in the background, to a very soft and almost indistinguishable edge on the outer part of the carte-de-visite, for which, and the imperial, this style of vignetting only is advisable.

## ON ALCOHOLIC ALKALINE DEVELOPERS.

BY PROFESSOR H. VOGEL.\*

ORDINARY alkaline development is undertaken with an aqueous solution of pyrogallie acid, ammonia, or carbonate of ammonia (or caustic potash), together with the addition of a small quantity of bromine salt. It is usual to moisten the dry plates first of all with alcohol, so as to render them more permeable to the developer; they are then washed, and the developer is applied. This washing operation causes a little trouble and delay, and I have sought to obviate these by employing an alcoholic, in lieu of an aqueous, developer, which may be applied at once, without any previous washing of the plate.

I mixed 90 cubic centimetres of alcohol, of 85° strength, with 10 cubic cents. of liquid ammonia, and added to this, for developing, pyrogallie acid and bromide of potassium, according to the following proportion:—

Ammonia solution	...	...	8 cubic cents.
Pyrogallie acid solution	...	...	6 to 24 drops
Bromide of potassium, or bromide of ammonium solution	...	...	2 to 3 drops

The pyrogallie acid solution is made up of:—

Pyrogallie acid	...	...	1 part
Alcohol	...	...	10 parts.

The bromide of potassium or ammonium solution is made up of:—

Bromine salt	...	...	1 part
Water	...	...	4 to 5 parts.

The plate is moistened with alcohol of 75°, first of all (with alcohol, therefore, of the same strength as the alcohol-ammonia solution,—an important point), and then, without being washed, treated forthwith with the developer.

The result I obtained by working in this way was, as regards clearness and uniformity, perfectly astonishing. I usually work with bromide of silver plates, which are sensitized in the ordinary silver bath, and washed, and with these I find aqueous development scarcely suitable, for fogging of the plate is apt to set in, as well as the formation of patches near the margin, when the finishing of the negatives has to be left to an assistant. The fog may, it is true, be obviated by a plentiful addition of bromide of potassium, but, unfortunately, the lack of bromide is found out too late, when the picture is already too much developed. These difficulties are overcome by the employment of an alcoholic developer. The picture, it is true, appears more tardily, as under the influence of an aqueous developer, and not with the same intensity, but then it is more under control. In under-exposed plates the bromide of potassium may be left out altogether, and yet, by the application of a strong alcohol, an absolutely clear plate, free from fog, be obtained. If a dilute alcohol solution is used, the development goes on more briskly, as under ordinary circumstances, but the result is not so clear. If, on the other hand, very strong alcohol is taken, the picture is a very long time coming, thus proving that it has a retarding action.

The intensifying of the negative is undertaken with six to twenty-four drops of pyrogallie acid, eight cubic cents. of alcoholic ammonia, without any addition of bromide. I have employed this alcoholic developer in a very large number of spectrum plates recently taken, and have

\* Photographische Mittheilungen.

secured results which would have been quite impossible to obtain with aqueous development.

I ought here to remark that certain bodies dissolved in alcohol greatly increased the retarding effects of the latter. To this class belong all aniline colouring matters, which, under certain conditions, I put into my dry plates. At first I allowed the alcohol from my moistened dry plates to run back into the stock bottle, and I remarked that as this became more and more deeply tinted by the colouring matter, so the developing action proceeded with more and more tardiness.

It is, therefore, well to moisten one's plates invariably with pure alcohol. As a particular advantage of alcoholic development I may mention that the film clings very tightly to the glass surface, even when no albumen or india-rubber stratum has been made use of; whilst in the case of an aqueous developer the film has a great tendency to slip off in the washing and fixing process.

The difference in the action of an aqueous and alcoholic developer may be explained simply by reason that the presence of alcohol renders the reducing action of the pyrogallic acid more difficult. It is well known that aqueous pyrogallic solution speedily becomes brown, the latter being oxidized by the oxygen in the atmosphere, while alcoholic pyrogallic solution may be kept for years without browning or oxidizing. This retarding action remains even in the presence of ammonia, being the more apparent the more alcohol there is present. It is, therefore, in one's power to regulate the rapidity of the development by the addition of more or less alcohol.

That the addition of a large quantity of alcohol renders the employment of a bromine salt unnecessary is due to yet another reason. The bromide of silver film always contains a small quantity of free nitrate of silver, which raises its sensitiveness in no little degree. The aqueous ammoniacal developer has a tendency to dissolve the nitrate, and when this happens, a fogging of the plate ensues, for pyrogallic acid with ammonia brings about a general reduction of the very easily reducible nitrate of silver in solution. The addition of bromide of silver hinders this, by converting the nitrate of silver at once into bromide of silver, which is less easily reduced. Alcohol may be substituted for bromine salt, as it dissolves nitrate of silver with difficulty, and thus prevents rapid reduction, in accordance with the saying, *corpora non agunt nisi fluida*. For this reason the addition of bromine to the developer is less necessary in a strong than in a weak alcoholic solution. Aniline colours act in the same way, but have a stronger retarding action than alcohol.

PREPARATION OF ABSOLUTE ALCOHOL.

BY J. LAWRENCE SMITH.\*

This substance, as obtained in commerce, very seldom marks more than 98 to 99 per cent. It is, however, not unfrequently made in our laboratories, and when this is done the usual method is employed of pouring strong alcohol on lime until the lumps of lime are covered. This method of proceeding gives a thick magma which, when heated over a water-bath, allows the alcohol to pass over but slowly, and much of the alcohol is lost from the impossibility of the heat penetrating the thick mass. The method I follow differs from this in no way except in the quantity of lime employed; using the smallest quantity of lime necessary to abstract all the water, it is surprising how completely the lime will perform its function in this respect. Take, for instance, one litre of alcohol of 94 per cent.; this contains about 60 grammes of water; if to this be added 120 grammes of good and fresh-burnt lime, requiring about 40 grammes of water to convert it into hydrate, actual experiment proves that when kept in con-

tact with the alcohol a sufficient length of time it accomplishes this absorption of water, and the alcohol decanted from the precipitated lime will be fully 98 per cent.

Operating upon this fact, I have been long in the habit of supplying myself with alcohol of 98 and 100 per cent., by proceeding in the following manner:—I have in my laboratory three or four 2-litre bottles, into each of which I place 1½ litres of 94 per cent. alcohol, the strongest alcohol sold in commerce; to this is added 180 grms. of fresh-burnt lime, of the best quality, broken up into a coarse powder. These bottles are set aside on the shelf, and agitated from time to time: the oftener this is done the more rapidly will the reaction be accomplished. A week or ten days will usually suffice when the bottles are allowed to remain at rest, and the hydrate of lime will settle in a few days, and by a syphon two-thirds of the original alcohol can be drawn off free from lime, which marks 98 per cent. alcohol, and when filtered and 50 c.c.m. evaporated to dryness there will be left only the merest trace of lime, less than ½ milligramme. But, of course, redistillation is so simple that if we wish the alcohol at 98° it can be readily distilled over a water-bath. The magma remaining in the bottle, when distilled over a water-bath, furnishes the remainder of the alcohol about one half per cent. higher.

When absolute alcohol is desired, take the alcohol just as it has been syphoned off or distilled from the magma, put it in a convenient flask for distillation, and to each litre add 120 grms. of lime in coarse powder; attach to a Liebig condenser inverted, so that the alcohol will run back into the flask when condensed: this is continued for an hour and a half or two hours. The condenser is then placed in its normal condition, and alcohol distilled over which will mark 100 per cent. Recently I have learned that there is a method adopted of making the absolute alcohol by one distillation, operating by the inverted condenser first; but in this process the amount of lime called for is the usual quantity, whereas I find that by reducing the lime to its minimum, and always having bottles ready to furnish 98 per cent. alcohol, the operation is facilitated, and the loss diminished. So that with the ordinary conveniences and appliances of the laboratory, that are always at hand to be mounted, I can, with fifteen or twenty minutes of *personal attention and manipulation*, obtain a litre or two of absolute alcohol. Of course the time for the reaction of the materials and the distillation is not referred to, as this requires little or no supervision.

A RAPID DRY-PLATE PROCESS.

BY H. T. NEWTON.\*

SINCE writing on this subject I have continued my experiments, and have some modifications to suggest.

The No. 1 collodion should have one and a-half grains of chloride of calcium instead of one grain. The developer is compounded as follows:—

Water	...	...	...	...	3 ounce
Ammonia	...	...	...	...	1/4 "
Bromide of ammonium	...	...	...	...	10 grains

To develop an 8 by 10 plate, put three drops of the above into a wide-mouth vial. After washing the plate thoroughly, flow over it three-quarters of an ounce of a three-grain pyrogallic acid solution. If the exposure has been right, the image will appear immediately. After the detail is well out, pour the pyro solution into the vial containing the alkaline compound, and again flow over the plate. The image will instantly assume strength and brilliancy. It should be finished with acid pyro, or tannin and pyro, in equal parts. The quantity of the alkaline solution to be used will depend upon the exposure. One drop will be sufficient, if the exposure has been one minute with a quarter-inch opening in an eight-inch lens.

## THE INFLUENCE OF COMPETITION FOR PRIZES.

As we have reason to believe that the offer of prizes by Mr. Crawshaw for specific excellence in photographs will not be renewed again for the present, a brief glance at the influence of the competition during the past two years may not be without interest. In some degree the whole question of the influence of contests for prizes is involved in the consideration of any special competition; but it is unnecessary here to do more than glance at the general subject. The opponents of medals and prizes allege that the disappointments, the bitterness, the heart-burnings involved, to a large number of competitors, far outweigh the value of the pleasure conferred upon the few successful prize takers. It is simply necessary to point out that the aim of such competitions has no reference whatever to the amount of gratification to which they shall give rise. Their object, besides the generous general aim to aid a favourite art, is, we take it, twofold: first, to stimulate a number of artists to make special efforts to produce the very best work of which they are capable of a given kind; and, second, to ascertain the highest possibilities and secure the highest results, in a special branch of work, which can be produced under pressure of a strong, direct incentive to effort. Palms and gladness to the victorious necessarily follow: disappointment, mortification, irritation—the emotions varying in different mental constitutions—inevitably fall to the lot of the greater number who are behind in the race. Disappointment at failure is natural and right. No man sends in his contributions without hoping to win, and believing that he may do so. If he be indifferent about failure, he is scarcely worthy of success; the true conditions of emulation have not been aroused in him. Disappointment at failure is one of the essential conditions which in a competition should secure good results, because, in noble natures, that disappointment is the truest incentive to additional effort. The misfortune to be deprecated is when disappointment leads to bitterness or anger: the cases are happily rare, and the feelings, when evoked, fortunately much more transient than the real good effected.

In the Crawshaw Competition incentive was offered to the production of a class of work of a very unusual—we might almost say of an unknown—kind. So far as we know, life-size heads, produced direct in the camera, had never been attempted, certainly never exhibited, before. Mr. Crawshaw had himself made some effort in that direction with sufficient success to make him wish to see what

more could be done when a number of men made special effort; hence, for heads of this kind, he has during two successive years offered prizes of fifty and five and twenty pounds; and for heads of half life-size, prizes of half the amount; whilst, to admit of comparison, a prize for enlargements has each year been added. The results have been singularly interesting and instructive, whatever may be the conclusions drawn from them, which will necessarily vary with the tastes and mental stand-point of the observer. It is certain that many of the direct pictures have had more beauties and fewer defects than many photographers would have been, *a priori*, prepared to expect. That some distortion should arise from bringing the camera, with its huge Cyclopean eye, within a few feet of the sitter, was inevitable; but the distortion and the rugosity of texture have been much less obtrusively apparent than might have been anticipated. In choosing between direct life-size and enlargements to the same proportions, it is probable that where delicacy and refinement are regarded as paramount qualities, the enlargements would receive the preference; whilst for vigour, massiveness, and bold relief, many would prefer the direct pictures. The examples of the latter probably in no instance had quite so much of the ameliorating labour of the artistic pencil in softening asperities as the majority of the enlargements had received, and this modifying treatment, it appears to us, is imperatively necessary in all life size photography. As we have before insisted, the literal imitation in full proportions of life, of every line, every creckle, every variety or defect of texture, petrified into perpetual rigidity, without colour, without anything of the generalization of the many phases of thought and feeling which pass over every face in a few minutes, and which the true artist blends into one harmonious life-like aspect—is at times absolutely painful. There is every detail of life's form, but no life; often strikingly illustrating Byron's lines:—

"So coldly sweet, so deadly fair,  
We start, for life is wanting there."

The skilful artist softens, blends, subdues, the rigid details, and gives the photograph the quality of a pictorial presentment of life, rather than a stark imitation of life. And this, in our estimation, is one of the important lessons of the competition. And whilst it has been shown that portraiture, even in life-size, under skilful and judicious treatment, may be satisfactorily produced in the camera, it has been shown that in half-life size, of which comparatively little has been done before, the results are exceedingly charming, for in this size, with scarcely a single exception, the examples sent in to both competitions were in every way admirable.

Besides giving the photographers an interest in, and familiarity with, portraits of more important size, and showing them and the public to what extent photography could successfully attempt such work, there have been many collateral advantages gained. Every photographer who has entered the competition has gained something in the effort. Increased knowledge of and mastery over technical conditions, under circumstances of an unusual kind; increased art knowledge and experience: light and shade are the chief elements of pictorial art of which the photographer can effectively avail himself, and the management of these elements in large heads makes more serious call upon the photographer's artistic skill than is done by small pictures. Hence freedom of style, largeness of idea, escape from the pettiness of conception, which perpetual concentration upon small work is apt to produce, are amongst the general advantages secured. These and other gains, which we need not pursue further, have unquestionably been amongst the collateral advantages of the competition. And the least of these is of more importance, and will be more enduring in its character, than the memory of any of the few minor disappointments or jealousies which have arisen, and will leave in the mind of photographers and that of the munificent donor of the

prizes only the memory of the beneficial results to which the competition gave rise; whilst the name of Mr. Crawshaw will always be associated with his noble and disinterested aid in giving an important impulse to this branch of the art.

#### TRADE ALLUSIONS IN PHOTOGRAPHIC MEETINGS.

A QUESTION of some interest to photographers, which has before been discussed, has again arisen out of the proceedings of the last meeting of the Photographic Society. A correspondent, who had been present at the meeting, complained in our pages a fortnight ago of the tendency, in the papers and in the discussions, to trade allusion, and the distinct mention and recommendation of the wares of different manufacturers. The adoption of any precise, inflexible, and unvarying course in such matters is fraught with many difficulties. The primary aim of all the proceedings at Society meetings is to give useful or interesting information to the members; and many members are interested in knowing the especial lens, collodion, or other appliance with which a given result was produced. To say that such information absolutely should not be given, because it involved the mention of a special manufacturer's name, would be manifestly to attempt a degree of repression in every way offensive and undesirable. To permit, on the other hand, the constant introduction of announcements, recommendations, or "puffs" of the wares of special makers, by a side wind, into papers or discussions, might become a serious injustice to other manufacturers, who, more modest, or less fortunate in having eloquent friends, or less shrewd in securing such advocacy, would, with equal claims, receive no such aids to publicity in the Society meetings. The admirable institution of a technical exhibition at the South London Society was nearly swamped in its youth by the tendency manifested last year to use it for trade purposes. To avoid all the risks attendant on such a course, it is the custom of many scientific societies to prohibit trade allusions altogether. In the Photographic Society of London it has been the custom, without absolutely forbidding such allusions in discussion, to check the tendency as far as possible; and this has been best effected by the elimination of allusions of an advertising character, from any papers in which they might occur, previous to their being read to the meeting. Unfortunately this had not been done on Tuesday evening, the transition state of the Society, and the change of officers involved, affording, we presume, the explanation. As this unsettled state of things will, we trust, speedily pass away, we may fairly hope that the evils dependant upon it will pass with it, and that this particular evil will not occur again. The tendency to indulge in trade talk at the last meeting has been the subject of condemnation in various quarters, as our correspondence columns bear witness. We note, also, that in a contemporary it is the subject of econdemnation; but, oddly enough, the strictures are confined to the remarks of one gentleman, who is described as sneering at the tools of a successful rival, and pulling the lenses of an eminent manufacturer. As this gentleman did not initiate the mention of the works of special manufacturers, but hearing of the long exposures required by the lens of a French maker, whose name, amongst those of other manufacturers, had been mentioned, he, having much experience in the special class of work, gave the information that by the use of another lens a very much shorter exposure would suffice, it is hard to see in what especial sense his allusion could be regarded as "putting," if those which had preceded it were innocent. Of the sneering alluded to we neither saw nor heard anything. Mr. Mayland, in an earnest and indignant letter in another column, points out that Mr. Chaffin was in no way blame-worthy for mentioning his lens maker, collodion maker,

and paper maker, as he was inexperienced in the practice of the Society; but that some one manifestly was blame-worthy. It is quite certain if the subject had not been introduced, Mr. Robinson would not have initiated the trade allusions which his good-natured desire to give information led him to follow; and he will probably be as much surprised, and possibly more amused, than any one else who was present at the meeting, to learn that his kindly remarks are reported as sneering at a rival's tools.

#### FRENCH CORRESPONDENCE.

So as not to extend too much the subjects treated of in my last letter to you, I will merely quote the formulæ by means of which M. Geymet prepares, sensitizes, and develops the plates which, under the three monochrome clichés of M. Ducos du Hauron, yield at once coloured images. The collodion used is composed of—

Alcohol ... ..	100 cubic cents.
Ether ... ..	100 "
Pyroxiline... ..	3 grammes
Bromide of cadmium ... ..	3 "

The silver bath is prepared of—

Distilled water ... ..	1000 cubic cents.
Crystallized nitrate of silver	180 grammes
Nitric acid... ..	a few drops.

After sensitizing his plates, M. Geymet covers them with a preservative composed of—

Water ... ..	500 cubic cents.
Beer ... ..	500 "
Tannin ... ..	30 grammes
Acetic acid ... ..	50 "

After the solution has been made, the white of an egg is added, the mixture shaken violently, and filtered.

The developer is made up of—

Water ... ..	1000 cubic cents.
Pyrogallic acid ... ..	10 grammes
Acetic acid ... ..	5 cubic cents.

Before being applied, a few drops of a ten per cent. nitrate of silver solution are added. The fixing is conducted by means of a six per cent. cyanide of potassium solution.

The plates, which are obviously employed dry, should remain at least three minutes in the silver bath; when they are withdrawn, they should have a matt-white appearance, and look like an iodide film.

The cyanide, which will be seen to be very strong, attacks the image, and almost renders it invisible, but it soon reappears, and if the development is continued in the sunshine the maximum intensity of colour is obtained. M. Geymet employs very acid baths, because he finds he obtains, in this way, his colours more intense.

I mentioned, in my previous letters, the nature of the process which M. Ducos du Hauron employs, but I do not think it will be uninteresting to my readers to cite the theory which he has recently given me in a note just received from him.

A body that appears white to our eyes is one which sends back all the luminous rays falling upon its surface; a body that appears black is one which absorbs all the luminous rays and reflects none; and, finally, a body that appears to us coloured in such and such a manner is one which absorbs certain rays and reflects others.

Now it is well known that white light is composed of rays of different kinds, which may be reduced to three colours called primitive; to wit, red, blue, and yellow. A tint, whatever it may be, is always formed from one of these colours, or two or three combined in proportions which vary *ad infinitum*.

To copy a coloured painting, therefore, it suffices to reproduce by itself all the red (or compounds of red) of the picture, to do the same with the blue and with the

yellow, and, these three productions obtained, to blend them again in one sole image, so as to reconstitute the painting with all its combination of tints. Such is the principle upon which M. Ducos du Hauron's process rests.

In order to separate the three primitive colours in the model, he begins by making a first cliché, which furnishes him with all the red in the painting. To do this he interposes, as we know, between the object and the sensitive plate a plate of green glass. This colour having the property of absorbing all the red rays, there only pass through the screen rays of other colours, viz., the blue and yellow ones, or compounds of these two colours. By this first operation, therefore, we have obtained a cliché where the red and its compounds are all represented by transparencies, and the other colours by opaque portions in the film; and if a positive print is taken of this cliché (by the ordinary carbon process) upon red pigmented paper, a first image will be secured representing all that is red in the object to be reproduced.

Let us suppose now that a second cliché is made by substituting for the green glass an orange one. The exposure behind the orange glass is not so long as one might imagine; thanks to M. Ducos's improvements, only eight or ten minutes are necessary. A screen of this colour having the property of absorbing all the blue rays, this second cliché will furnish a positive which, produced by means of blue pigmented paper, will give all the blue of the model. And, finally, a third cliché obtained by employing a screen of violet glass (which absorbs all the yellow rays) will give a positive which, if produced upon yellow pigmented paper, will contain all the yellow or compounds of yellow in the original painting.

When the three prints have been thus obtained, it only remains to blend them together; that is to say, the impressions are produced upon provisional supports, and are then transferred to the same sheet of paper, care being taken to make them tally very accurately; the three monochromes thus superposed furnish a reproduction of the painting with all the tints of the original.

It is easy to understand that objects which in the original are black will be represented in each cliché by transparencies, and being marked upon the three positives, and with equal intensity, they appear black on superposition of the three colours, which annul each other reciprocally. The whites, on the contrary, being represented on each cliché by opaque portions, are not marked upon the positives, and are represented by the white paper serving as the ultimate support of the image.

The absorption of the red rays by the green glass, the blue by the orange glass, and the yellow by the violet glass, takes place in accordance with the law of complementary colours, and the results obtained by M. Ducos du Hauron confirm practically the scientific theories hitherto put forward on the subject.

M. Carette has presented to the French Photographic Society, on behalf of Dr. Van Monckhoven, some samples of sulphate of iron obtained by exposing a mixture of this salt, water, and acetic acid, for some days to a temperature of 100° Cent. in a closed vessel.

If this is added to a solution of ordinary sulphate of iron, such as photographers prepare, in the proportion of a tenth of the volume of this concentrated solution, it will be observed that the new developer possesses the following advantages:—1. It allows one to diminish the duration of exposure to one-half. 2. The image developed is much more intense. 3. The bath, instead of losing all its properties after a few days, gains, on the contrary, with age.

At the same time Dr. Van Monckhoven has remarked that the results vary according to the condition of the collodion, and especially that of the bath, and he promised to report further in the matter after some more experiments. Our friend calls attention to the circumstance now, as it is especially in dull weather that the new developer will be found most advantageous.

M. Franck de Villecholle exhibited to the members of the Society several enlargements obtained by the light of a sulphide of carbon or binoxide of nitrogen lamp. To regulate the flame, MM. Delachanal et Mermet have constructed an apparatus of the following nature, which M. de Villecholle has made use of:—

The binoxide of nitrogen produced by the economical process of M. Deville is saturated by sulphide of carbon vapour in a flask with double tubes full of small fragments of some porous body impregnated with sulphide of carbon. Into one of the tubes passes a current of gas, which descends to the bottom; into the other tube is fixed an iron pipe of very contracted diameter, made so as to prevent the flame returning towards the flask. The gas comes either by the first tube or by the second, and burns with the most brilliant blue flame. The jet has a large opening, and, whatever its shape, it must be provided with a stopcock to govern the flame, as well as to prevent it, at the end of the experiment, from approaching too near the orifices or tubes. The products of combustion—nitrogen, sulphurous acid, and carbonic acid—are dangerous to breathe; but they may be carried off by suitable pipes. The flame produced by MM. Delachanal et Mermet's lamp gives a blue flame extremely photogenic, and although it is not more than twenty-five centimetres in height, with a diameter of four or five centimetres, it is so soft as not to hurt the eyes.

The productions enlarged by the aid of this light are evidently superior to those obtained by other processes of amplification; but one cannot forget that, notwithstanding the improvements mentioned by our friend Franck, the illumination in question involves some dangers which photographers cannot but regard as serious drawbacks.

Toucheing this point, M. Pélégot, a member of the Institute, reminded the members of an accident which happened to Baron Liebig. The German *savant* employed, at a demonstration at which the Crown Prince of Prussia was present, a mixture of sulphide of carbon and binoxide of nitrogen. Despite all his skill and scientific knowledge, the illustrious professor could not prevent an explosion, the effects of which wounded the Prince. It is wise, therefore, to abstain from meddling with such dangerous compounds.

ERNEST LACAN.

#### LIEBERT ON PHOTO-ENAMELS.

FROM the negative to be printed a clear diapositive is obtained in the camera by means of a good collodion and properly acidulated silver bath, the plate being developed with

Distilled water	...	...	...	1 litre
Pyrogallic acid	...	...	...	6 grammes
Citric acid	...	...	...	4 "
Glacial acetic acid	...	...	...	30 cub. cents.

The image comes out slowly and with much delicacy; it must appear perfectly vigorous in the shadows and quite transparent in the high lights. It is fixed with cyanide of potassium, and thoroughly washed.

The margins of the collodion film are cut through, and the plate put into a litre of water containing six cubic centimetres of sulphuric acid; in a few minutes the image becomes detached, and floats upon the surface of the water. The collodion image is lifted by means of a glass plate and put into another dish, when it is washed with water half a dozen times.

For toning, two different solutions are required:

A.—Rainwater	...	...	...	100 grammes
Chloride of mercury	...	...	...	7 "
B.—Rainwater	...	...	...	400 grammes
Chloride of gold	...	...	...	3 "

Ten parts of A and of B are added to one hundred parts of rain or distilled water. The picture is put into this bath, and the grey tint soon changes to a deep black.

When it has become quite vigorous viewed as a transparency, it is well washed and put into a bath of

Rainwater	...	...	...	200 grammes
Ammonia	...	...	...	30 drops

In this the chloride of silver is dissolved, for if burnt in, it would impart a disagreeable tone to the picture. Finally, the image is again washed before it is laid upon the enamel plate.

During its sojourn in the furnace the image retains its black colour; if a sepia brown tint is desired instead, it is laid in a second bath prepared as follows:—

C.—Rainwater	...	...	...	250 grammes
Chloride of iron	...	...	...	2 "
D.—Rainwater	...	...	...	250 grammes
Red ferricyanide of potassium	...	...	...	2 "

These are mixed together in a flat dish, as under:—

Rainwater	...	...	...	300 grammes
Solution C	...	...	...	2 "
Solution D	...	...	...	2 "

½ per cent. solution of chloride of gold 2 to 3 drops

The picture is moved about gently in the dish so that it tones uniformly, and after two or three minutes it is thoroughly washed.

The laying of the picture upon the enamel is done in the following manner. The glass plate bearing the image is put into a dish filled with water, and the plate remains at the bottom, while the picture swims on the surface. The enamel plate is now slipped under the film, so that it is in its proper place, and then the glass plate at the bottom is lifted up and the whole taken out of the water. The picture is then carefully pressed against the enamel plate, so that any air-bubbles that are present are removed. The glass plate is held in a slanting position, to allow the water to drop off, and then the whole is dried over a spirit flame. After the margins of the collodion film have been cut away round the plate, the enamel is taken off the plate of glass.

The portions of tinted collodion film still adhering to the glass may be made use of afterwards in retouching. It is removed as soon as dry from the glass plate, and rubbed upon a palette with a few drops of lavender oil. As this retouching colour consists of the same elements as the picture, it possesses precisely the same tone.

The burning of the enamel takes place in a muffle furnace which is heated to a white heat by means of coke and small coal. The enamel plate is placed flat upon a round plate of clay, and it is brought in this way into the furnace. The collodion becomes brown, and then the plate is pushed further in, so that there should not be too sudden a change in the temperature at first. By degrees the high lights of the film become clear, and then the image is withdrawn slowly, allowed to remain for a short time at the entrance of the furnace, and then removed to get cold.

The picture is now burnt in, but possesses a matt surface; it still requires a ceramic glaze. This latter is prepared by mixing one part of easily fusible enamel powder (flux) with twenty parts of alcohol; the mixture is shaken up, and, after standing for some seconds, the upper portion is decanted off and mixed further with fifty parts of normal collodion. This is poured upon the picture, and the latter is drained against a bit of blotting paper, so that no thick edge of dry collodion is found at the margin. The picture, when the collodion is perfectly dry, is again put into the furnace, heated to a cherry redness in order to melt the flux. If the heat is not sufficient, the operation must be repeated.

*Process for large enamels.*—According to Duchemin, large photo-enamels are best produced upon glass plates which have been coated with fusible arsenic enamel. A plate of this kind is covered with a filtered solution of

Water	...	...	...	100 grammes
Gum...	...	...	...	3 "
Honey	...	...	...	1 gramme
Bichromate of potash	...	...	...	3 grammes

The film after drying is exposed under a diapositive, and then a powder of the following nature is applied with a dry brush:—

Oxide of cobalt	...	...	...	10 grammes
Black oxide of iron	...	...	...	90 "
Minium	...	...	...	100 "
Quartz sand...	...	...	...	30 "

The picture, when developed, is fixed by dipping in a bath consisting of one part muriatic acid in twenty parts of water, and then washed and dried.

The glass plate is put upon a cast iron plate covered with chalk, so that it may remain perfectly flat during its sojourn in the furnace. In a covered and well heated muffle the picture is burnt in within a minute; it should be cooled gradually.

SOME REMARKS ABOUT PHOTOGRAPHING INTERIORS, AND ABOUT PORCELAIN BATHS.

BY RANALD DOUGLAS.\*

A FEW weeks ago I was called upon to make some views of interiors whose light was so dim that my plates were covered with stains from long standing. I was about to give the job up hopelessly, when presently a bright idea occurred to me. I asked if they had any glycerine in the house. A small bottle of it was procured, and a few drops were put into my collodion and silver. The subsequent plates were free from stains, although left in the camera for from thirty to forty minutes. Curiously enough, the high lights, such as windows, bright objects reflected from mirrors, were distinctly visible on the plates just as they came out of the plateholder. The developer brought out the rest without fogging, save a slight veiling on the windows. This phenomena I never saw explained. Can any one explain it?

Mr. Carey Lea, in his excellent work on photography, says about porcelain baths: "If there is the slightest flaw in the glazing inside, the solution will penetrate it and gradually saturate the whole of the porous biscuit which makes the body of the vessel, between the inside and outside glazing. This not only involves a great loss of expensive silver solution, but after a time the outside glazing also probably cracks, and some day the operator finds his bath empty."

Last year I carelessly broke my rubber view-bath, and used a porcelain one in its stead, having before heard that silver would penetrate porcelain, but I thought my bath an exception. I trusted it with my solution over night, and even left it in for weeks. I suffered no inconvenience from it for about nine months, but lately, when taking a view, I noticed some diminution of solution. I suspected nothing, so re-filled it, and work went on. An hour after work was done, I returned to it and found it empty. This justifies what Lea says in his manual. Let those who use porcelain silver baths be careful to select perfect ones, or dispense with them entirely.

Correspondence.

KENNETT'S GELATINE PELLICLE.

SIR,—Surely Mr. Aldridge's letter, complaining that Mr. Kennett is out of pocket, is a little out of place. What are the facts? There is no "discovery" in the making of a gelatine emulsion, and Mr. Kennett patents, for his own use and benefit, the idea that for the convenience of a manufacturer desiring to supply customers, the gelatine shall be dried, as more convenient for carriage.

No photographer, amateur or professional, benefits by

\* *Photographic Times.*

this. Mr. Kennett has speculated in a patent, and must surely abide the results of his speculation.

He is indebted to other workers for the emulsion itself, and in my opinion should have considered this before attempting to take a patent. That the patent itself is not sound is no argument, one way or the other.—Yours, &c.

A WORKER.

### TRADE ALLUSIONS IN PHOTOGRAPHIC SOCIETIES.

"An Eagle towering in his pride of place,  
Was by a mousing Owl hawked at."

SIR,—Will you allow me very emphatically to endorse the protest of "N. L." in your issue of the 13th instant, against the practice of making papers read before the Photographic Society vehicles for trade advertisement? The practice is bad in itself, and brings a train of other mischiefs in its wake, amongst which "envy, hatred, malice, and all uncharitableness" are prominent, and these in their turn prompt the utterances of the "false witness." In the admirably brief, simple, and practical paper of Mr. Chaffin, there are no less than three such trade allusions: we are told from whom he obtains his paper, his collodion, and his lens. Mr. Chaffin was not to blame for this, but the officer of the Society to whose care his paper was committed previous to reading it was. It has hitherto been the wholesome custom to remove such allusions from papers previous to their being read to the members; and a rule of the Society makes it imperative that papers should be sent in a week in advance of the meeting, for the purpose of supervision and revision. I am the more forcibly struck with the evil of this trade puffing from what has followed, and which I also crave permission to protest against. At the meeting in question, after Mr. Chaffin had mentioned the lens he used, and stated that the exposure varied from seventy to one hundred and twenty seconds, Mr. H. P. Robinson suggested to him that by the use of another class of lens he might reduce his exposure to from twenty to thirty seconds. Coming from an authority of such experience and success in that, as well as other branches of the art, the information was interesting, and if the introduction of makers' names were admissible at all, most legitimate. I see in a contemporary journal a comment on the circumstance, which will pass for just what it is worth. But whilst we may pass the comment as unworthy of notice, I wish to enter my protest against the falsification of fact contained in the statement that Mr. Robinson sneered at the tools of a successful rival.

The statement is utterly without foundation. I was sitting at Mr. Robinson's side, and emphatically declare that there was nothing approximating to a sneer; but a quiet unobtrusive statement of a fact. The writer in question appears to be familiar with sneering, and affords a good example in his reference to Mr. Robinson as "a third place candidate for a prize," and this familiarity possibly made him impute his own practices to another. The sneerer is generally also familiar with the *suppressio veri* and *suggestio falsi*, and in this allusion there is an example of both. Instead of being simply a "third place candidate for a prize," Mr. Robinson took four prizes, the first prize in three classes, and the second in another. I have ventured to make this protest in the interests of the Society, as I know that nothing will so much tend to suppress discussion as the knowledge that the speaker is liable to false and malicious comments and misrepresentations in the journals.—I am, sir, yours, &c.

WILLIAM MAYLAND.

SIR,—Will you allow me to say that I feel much obliged to Mr. Fry for his assurance that a "genuine revival has begun" in the Photographic Society? The sole aim of my letter in a recent number was to secure a "revival" of the good old custom of "sinking the shop" when taking part in Society proceedings. I have always understood that a

rule or custom prevailed of removing everything like trade advertisements from papers before they were read, whilst I certainly have not heard so much *shop* at a meeting of the Society for many years as I heard at the last; and I should be sorry indeed if its tone and manner were to become the keynote for others to come. Some of the new members who had come up from the country to attend the first meeting of the session expressed their disappointment and disapprobation emphatically at its close whilst in the room, and remarked that they would not travel many miles in a hurry to hear nothing but shop and triviality.

I must decline to discuss the qualities or conduct of the chairman, as I never denied his geniality, and should not, in any case, begrudge him the approval of Mr. Fry.—Yours truly,

N. L.

### DISPENSING WITH WATER IN OUT-DOOR WORK

SIR,—Will you kindly allow me space in the NEWS to state that the method of dispensing with water in out-door photography by means of the acetic acid and water preservative which Mr. Viles, in his paper read before the Photographic Society of Great Britain, has attributed to me, is the process that Mr. B. J. Edwards gave to the photographic public when he described his Graphogene before the South London Society.

Your insertion of this will confer a favour upon—Yours respectfully,

W. T. WILKINSON.

14, South Street, Bromley, Kent, Nov. 23rd.

### Proceedings of Societies.

#### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of this Society was held at the Free Library, William Brown Street, on Tuesday evening last, the 24th inst., the Rev. J. D. RILEY, Vice-President, in the chair.

The minutes of the previous meeting were read and confirmed, and Mr. B. Boothroyd and Mr. W. M. Pendlebury were elected members of the Association.

The SECRETARY then read his

#### Annual Report.

In presenting the eleventh annual report of the proceedings of this Association, I am pleased to say that there is no falling-off in its prosperity. Seven new members have joined, and only two resigned.

The attendance of the members is generally good; but I think it would be advisable to meet a little earlier in the evening, for many members who live out of Liverpool leave business some time before the usual hour at which our meeting commences, and, rather than wait in town, proceed home, and then feel disinclined to return to town again for our meetings.

In looking over the work of the past session, I find that few papers have been read, members frequently stating that they had nothing new to communicate; yet the meetings have been plentifully provided with objects interesting to photographers, and, with but little trouble to the exhibitors, instructive papers might have been written on their methods of production.

A paper on the "Emulsion without Washing Process" has been communicated by Mr. Phipps, and by this process both Mr. Phipps and Mr. Houlgrave have experimented and produced most excellent results, which have been exhibited at the meetings.

The gelatino-bromide process has been described and illustrated by Mr. Palmer and Mr. Atkins, the President, at our first meeting, practically illustrating the development of the plates.

Various articles of apparatus connected with photography have been shown by Mr. Ellerbeck, Mr. Keith, Mr. W. Harding Warner, and others.

Mr. Atkins gave an exhibition of transparencies by the aid of the sciopticon.

Prints and negatives by various processes have also been plentifully exhibited, so that the meetings have always proved interesting.

The Society's album has received several contributions from Mr. Green, Mr. Warner, and others.

The usual presentation plate is this year again wisely printed in carbon, with an addition of four smaller prints by the Woodbury process, so that members may possess a reliable example of the progress of permanent photography.

It has not yet been found practicable to illustrate the actual working details of a process at the evening meetings, owing to the difficulty of procuring suitable conveniences.

The Edinburgh Photographic Society have what are called "popular evenings" occasionally, at which there is a lantern exhibition of photographs, with a descriptive lecture. It would, no doubt, be advantageous to this Association if one or two exhibitions of this character were given to the members and their friends during the winter season.

Only one outdoor excursion has taken place this season, which was to Rhydywyn; but many of the members usually take advantage of the facilities afforded by the excursions of the Naturalists' Field Club, and manage to secure excellent pictures.

The TREASURER then read his report, showing a balance of £25 3s. 5d. to the credit of the Association.

The Rev. T. B. BANNER said the reports of the Secretary and Treasurer were exceedingly satisfactory, and they were passed.

Mr. W. H. WILSON thought it was advisable, as the Secretary had suggested in his report, to meet earlier in the evening. He proposed, therefore, that the meetings should commence at six o'clock.

The motion was agreed to.

The VICE-PRESIDENT proposed that there should be a lantern exhibition for the members and their friends.

The Secretary was requested to make arrangements for such exhibition about the middle of January next.

The following officers for 1875 were then elected:—*President*—Rev. J. D. Riley. *Vice-Presidents*—Mr. W. Atkins and the Rev. H. J. Palmer. *Treasurer*—Mr. A. Tyrer. *Hon. Secretary*—Mr. W. Murray.

Mr. E. Roberts, Mr. E. P. Houghton, and Mr. W. H. Kirkby were then elected members of the Council in the place of those retiring by rotation.

The third number of the Belgian *Bulletin* was handed round. It was illustrated with a charming portrait, printed in carbon, by Mr. J. Maes, of Antwerp.

The Rev. H. J. PALMER exhibited the plan he adopted in preparing and coating his gelatine emulsion plates. He had made a raid on the nursery, and captured one of Clark's pyramid food warmers; this he found admirably adapted for the purpose of keeping warm and pouring on the emulsion, as by using it several disadvantages in using a bottle were avoided. He (the Rev. H. J. Palmer) also described the cupboard in which he kept his plates, which, however, were a long time in drying.

Mr. O. R. GREEN said that that would be owing to the cupboard being air-tight; and the plates being wet when put in, the air in it would keep damp. If, however, a few pieces of lime were placed in it, and covered with calico or blotting-paper to prevent dust, he had no doubt the lime would absorb the moisture, and the plates would dry much quicker.

The SECRETARY exhibited some specimens of the plumbago or "dusting-on" process, done by Mr. W. B. Bolton and himself, and advised the members to try it themselves.

Mr. ATKINS showed some developing dishes for gelatine plates made by cementing strips of glass on another piece somewhat larger than the plate to be developed. By using these dishes he was enabled to cover the whole of the gelatine plate, otherwise he had great difficulty in making the developer flow all over.

The Rev. H. J. PALMER said that by putting a few grains of plain gelatine into the emulsion he found no difficulty in making the developer flow even to the edges of the plate.

Mr. ELLERBECK used the plain gelatine before applying the developer with good effect.

Mr. WILSON proposed, and Mr. ATKINS seconded, a vote of thanks to the Library and Museum Committee for the use of the room for the meetings. The vote was carried by acclamation.

The meeting was shortly afterwards adjourned.

#### WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

THE next meeting for the 30th inst. (Monday) will take place at Leuchter's Rooms, opposite the Mechanics' Institute, Bradford, at 7:30 p.m.

The report of our last meeting, unfortunately, was not inserted in the PHOTOGRAPHIC NEWS issued on the 20th inst. I obtained half-a-dozen proof reports of our meeting, and distributed them to the Yorkshire local newspapers. In my great anxiety to give publicity to our first and very successful inaugural meeting, the mistake arose owing to the proof for your journal being enclosed to me, and sent by mistake to a local paper, whilst I expected it

would have been forwarded to you direct. However, the readers of your journal will be in time to attend our next meeting as above stated; and as our committee is formed with the intention of adding three additional names that will represent the photographic interest of any towns that may be pleased to ally themselves with Leeds, Bradford, and Halifax, intending members please will take this as a personal invitation to attend on Monday next.

To the two or three gentlemen in Leeds who have expressed a little surprise that they were not invited personally, it will perhaps be necessary to explain that the Society, having no "body" to move in the matter, was comparatively powerless to wait upon gentlemen as etiquette would require, and therefore dependence was placed upon photographic gravity alone for drawing its members together.

I may add that the West Riding Society has now a body, and, if not a soul, a very earnest spirit; and as to the former, it is increased, to my hearing, this last week by a dozen new members at least. The "good wishes" letters that reach me are very encouraging; but the one dated from Mr. Cumberland contains a very practical suggestion—"Put me down as a member"—a formula I now give to future correspondents.—I am, yours, &c.,

J. W. GOUGH, Hon. Sec. pro tem.

### Talk in the Studio.

**NITRATES IN THE PRINTING BATH.**—Alluding to a recent reference in our pages, by our Paris Correspondent, to the use of nitrate of potash in the printing bath, *Anthony's Bulletin* says:—"We would suggest that the nitrate of potash could profitably be replaced by the nitrate of alumina, which could be used, in consequence of its great astringent quality, in much less proportion than the nitrate of potash. Any one desirous of trying the nitrate of alumina can very easily prepare it by dissolving chalk in nitric acid to saturation, filtering, and then adding to it a saturated solution of alum until the precipitate of sulphate of lime ceases. The remaining liquid is a solution of nitrate of alumina and nitrate of potash. A weak solution of this salt can also be employed to prevent the blistering of the albumen after removal from the hypo. After the prints are toned, and before putting them in the hypo, allow them to lie some time in a weak solution of nitrate of alumina. This will have the effect of so hardening the albumen as to prevent the solvent action of the hypo upon it. Too strong a solution of nitrate of alumina will cause the albumen to crack."

**GLYCERINE PRESERVATIVE.**—Mr. B. S. Cooper, writing in the same journal, says:—"It frequently happens during the hot summer months that we have to go out to take monuments, and sick or debilitated people, but find in such places no means of developing. Such has been my experience this summer, which led me to make some experiments in order to keep the collodion moist. I tried several means and ways to no purpose, until I tried the following: pure glycerine, 1 ounce; condensed water, 1-2 ounce; shake well, and after the plate is coated, drain and wash with clean soft water until the greasy lines are nearly all gone; then pour over it the glycerine on and off, till all the lines are gone. Let it drain for a time, and place it in the shield. It will keep moist for three or four hours, with the thermometer at 104°; the time required is from fifteen to thirty seconds, according to light and stop used in the lens. I develop with iron, rather weak at first, 12 grains to the ounce; I use glacial acetic acid, 2 ounces to 24, until it penetrates the film; then I add silver, 5 grains to the ounce, pour it over the plate, when to my delight the picture comes out boldly and clearly. In order to get up intensity, add more iron and silver, after which treat it as usual with negatives. Any mode of developing generally practised will do, with the addition of silver; but, without it, there is only a faint outline of a picture. I have never seen this recommended in any of the journals, but hope it will be fully tested by more skilled hands."

**DRYING AND FUMING SENSITIVE PAPER.**—A correspondent of the *Philadelphia Photographer* says:—"A good drying and fuming box may be made as follows:—Take a common dry-goods box about three feet long and twelve by twenty inches deep and wide (size not particular); make a door of the top, and paper inside and outside; set on end in a dry room. When the paper is silvered it should be hung up to drip, silver side

out, and, to prevent curling, fasten two corners together by means of pieces of cardboard one and one-fourth inch long by half an inch wide, and cut one-third their length like a pen. Put this split card on the two corners, which will hold them in position; attach, also, a small piece of filtering or tissue paper to the lower corner, to carry off the drop. Across the top of the drying box stretch two wires, equi-distant from the front, back, and each other; on these wires spring clothes pins should be placed so as to move easily wherever wanted. Eight inches from the bottom a piece of wire-cloth should be stretched the full size of the box. When the paper has ceased dripping, place two pieces back to back, fasten two or three corners, according to the size, with the cardboard already described, and suspend by the clothes-pins on the wires. If large, suspend by two pins; if small, one is enough. Heat is produced by an alcohol lamp under the wire-cloth, which diffuses the heat uniformly. Dry in ten minutes. When dry, remove the lamp, and in its place put the ammonia for fuming. When fumed, opening and shutting the door violently will expel the excess of ammonia, and the paper may remain in the box until wanted. Paper rapidly dried in the dark gives more brilliant prints, and is more sensitive. Paper kept long in a very dry room has the peculiar property of not printing until some hours after silvering; the same paper hung in a damp room over night, and silvered as usual, will print all right. Paper prints most brilliant when just dry enough not to stick to the negative. If very dry, it prints harsh, and will not take a pleasant tone. Too dry paper gives prints lacking detail in the shadows and softness in the high lights—dead-looking prints."

## To Correspondents.

**THE YEAR-BOOK OF PHOTOGRAPHY FOR 1875.**—We have pleasure in acknowledging the receipt of copy for our forthcoming annual from many of our friends, and we take occasion to appeal to all our readers whose experience and observation may have suggested interesting points of practice, to favour us with brief statements of such matters, to enable us to make our forthcoming YEAR-BOOK as complete and interesting as possible.

**G. MACKIE.**—As a rule, we have found that the defect you describe, of the prints which appeared sufficiently deep in tone whilst in the gold bath, becoming brown on fixing, is due really to insufficient toning, the eye being deceived by the apparent depth; and the remedy in such case is simple: it is only necessary to carry the toning further, and allow the prints to become apparently too black in the toning solution. In this case they will lose something in the fixing bath, but will possess sufficient depth when finally dried. Sometimes it is due to rapid toning, giving a rapid superficial effect of richness, which is lost in the hypo. In this case, using the bath somewhat weaker is the remedy. Very frequently it is due to the use of a weak, flat negative, which does not permit sufficient depth in printing without overdoing the lights. A good brilliant negative is an essential requisite to the production of rich purple tones. In some cases you will find that the first effect of redness caused by immersing the prints in the hypo disappears on allowing them to remain in the fixing bath a little longer. The maker of the paper you mention recommends a tungstate of soda and gold bath, using twenty grains of the tungstate, one grain of chloride of gold, and six or eight ounces of hot water, using the bath as soon as it is cold. Have you tried this?

**JAMES MAYCOCK.**—The "Kineoscope" was a pretty little photographic toy invented in France by Mons. Langlois, and patented both in France and this country. It practically afforded an interesting illustration of the persistence of vision. It consisted in a little locked containing two minute photographic transparencies placed opposite a Stanhope lens. The pictures presented the same object in two different positions, representing two phases of one action. On looking through the small aperture of vision the figure is seen in one position, but on depressing a small button this figure disappears, and another appears in its place, in another position, with such rapidity that the figure seems to be changing its position. An example we have seen, presented, in the first picture, a gentleman and lady apparently conversing; a touch of the button represented them kissing, and a rapid motion of the button gave the effect of a rapid succession of kisses being exchanged! Of course an endless series of effects of motion could be produced with suitable pictures. The name was not derived from the inventor; its derivation, so far as we remember, was from the Greek, and referred to the illustration of motion which the optical toy afforded.

**B. C.**—As a rule, it is a well understood practice amongst respectable professional photographers not to exhibit portraits in a show-case against the expressed wish of the customer. We do not know of any especial method by which you can absolutely compel the photographer, who is imprudent enough to persist in exhibiting a portrait after your decided prohibition, to remove it. It is probable that a lawyer could help you to a remedy; but we cannot indicate the precise proceeding. In the only case of the kind which we remember to have seen, the sitter whose portrait was exhibited against his will broke the show-case and removed it, a plan which we can scarcely recommend.

**H. NORGATE.**—We regret that we cannot give you the information. We do not at present remember any one who gives lessons in colouring photographs.

**F. STEPHENSON.**—We see no reason to suppose that the lens is much in fault; but it covers only a small field, and must be used for small pictures. There is a little tendency to under-exposure in the pictures, and they are not well lighted. The view of the Waterloo Hotel is pretty good; but the other building is under-exposed, and stained, either from a dirty plate or imperfect manipulation. The child's portrait has apparently been taken in the open air, which does not permit of the same effective lighting which can be secured in a studio. You should remember, also, that in taking either buildings or landscapes a suitable time of day and condition of light should be selected, in which well marked light and shade can be secured, as an even, diffused, dull light gives tame, flat pictures.

**W. H. B.**—The address of Mr. Viles is Pendryl Hall, Codshall Wood, Wolverhampton.

**ONE IN THE DARK.**—There is no work solely devoted to the chemistry of photography; but you will find much valuable information in Captain Abney's Instruction Book, which is cheap; or in Anderson's "Skylight and Dark Room," at a higher price.

**H. S. (Brighton).**—Streaks in the direction of the dip arise from various causes; but you will find that they very frequently arise on first replenishing an old bath with new solution, and will in this case very often disappear after a few plates have been worked in the bath. A very common cause, often overlooked, is the presence of floating scum on the surface of the solution. When the solution is left in the bath it is a wise course to take a strip of clean blotting-paper and remove all traces of such scum every morning. When the streaks arise from something not easily traced in the constitution of the bath, it is a good thing to keep the plate in motion laterally all the time it is in the bath. At this season of the year it is not uncommon for streaks to arise from immersing the plate before the collodion film is sufficiently set. Sometimes diluting the collodion with a little plain undiluted collodion will remove them. The brownish stains on some negatives are apparently caused by an imperfection in the albumen coating, some floating filament having probably been present in the albumen solution, which would, by the way, be better made weaker. The image being poor, and the deposit sandy, suggests an over-worked bath.

**ENQUIRER.**—The tear-drops on your negatives are probably caused by splashes of the nitrate solution from haste in pushing down the slide of the camera-back.

**JARLEY.**—As a beginner in photography, reading the News will doubtless, as you anticipate, aid you much, and we shall at all times have pleasure in giving you information and advice. There are various modes of preparing plates so that they will keep for a few hours; but if you wish to keep them more than a few hours it will be wiser and easier to try a dry process. One of the simplest plans of preparing a plate to keep a few hours is to proceed in the ordinary mode of coating and sensitizing the plate in the silver bath, and then wash it in two or three changes of water, the first being distilled water. Then pour over it a mixture of equal parts of glycerine and water, and place it away to drain in the dish. Such a plate may be used, perhaps, twelve hours afterwards with safety. Expose two or three times as long as with a wet plate in its ordinary condition. Before developing, wash away the glycerine coating, and cover the plate well with a little of the bath solution, then develop as usual. Most preservative processes are often uncertain, and always messy and troublesome; spots and stains often arising from various causes. A simple dry process is more certain. The coffee process, or the beer and albumen process, or the Pothergill process, would be easily mastered. You will find these all in our last YEAR-BOOK, which you will find of great service to you.

**J. TAYLOR.**—A half-plate lens may be used in its complete form with the lantern. A 4½-inch condenser will do well. Mr. York's address is 87, Lancaster Road, Notting Hill.

**A CONSTANT READER.**—We do not remember the dates with certainty, and have no files for reference. That in the *Times* appeared on the Saturday previous to its appearance in the *News*. The *Standard* was earlier, being within a few days of the opening of the exhibition.

Several Correspondents in our next.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

#### THE PLEASURES OF A STEREO-STAND AND GLASS SLIDES.

"I SHALL not go abroad next summer, but spend twenty pounds on one of these revolving stereo-stands and a lot of glass slides." And our friend, sitting comfortably in an arm-chair, with his elbows resting on the table, continued to gaze with deep interest at the views as he turned the handle of the instrument. "There's the *Mer de Glace* at Chamounix. Why, I can almost see that part of the glacier I crossed. And that's Geneva, with the bridge where you look down and see the rapid Rhone hurrying along at your feet. Ah! there's the old lion at Lucerne carved out of the solid rock, in memory of the Swiss Guards killed at Paris. I know this; it is Genoa. By Jove! I remember walking along that very quai past the big church at the corner. And this is the Hall of Mirrors at Versailles; it is like looking through a hole in the wall right into the place," &c. &c. And thus our friend proceeds to recognise, one by one, the pictures of places more or less familiar, the brilliant transparencies showing every detail as clearly as they are to be seen in the original. "But why are the little pictures so expensive, and why are they to be purchased only in Paris, and from one firm alone?" Well may our friend ask the question. The work of this kind done by our own artists—by Bedford, England, Gordon, Good, and many others—is quite equal to that of the Paris photographers, and it is only the matter of printing transparent positives which appears to be the difficulty. And this is certainly no insurmountable one, for there is not one, but three or four good and practical methods now-a-days of producing such transparencies. The true reason why we leave the matter undisputed in the hands of the French is to be found, we think, in the want of a venturesome publisher. A large amount of capital would be necessary in producing an extensive collection of pictures, but we cannot help thinking that there would be little of the speculative about such a venture. People may get as tired as they like poring over paper pictures with a stereoscope placed at an awkward angle on the table, but a glass slide is quite another matter. Not only is it always seen to best advantage in the same position—viz., against the light—but, from the fact that a photograph never shows to such advantage as a transparency, the picture is always better worth looking at. Paper stereograms may be of any quality, but the Paris glass slides are all of them of a superior kind. They are too good to become common, and they are far more satisfactory to the traveller who knows the spots they tell of. The stands, holding some fifty or sixty slides, are, at the present moment, rather expensive articles of drawing-room furniture, for none of the glass pictures, we believe, sell for less than five francs each. At the same time there are many people who eagerly give this price, as there are who purchase Breeze's well-known pictures for three or four times the amount. But transparent slides of English scenery do not exist, at any rate in any number, and the purchase of them is almost an impossibility. In no other form is a photograph so interesting as in this, and if you are a traveller you are never tired of looking at pretty places you have visited. How often do we delight in a certain happy thought, passing away instantly, that reminds us of this or that portion of our travels! The feeling comes over us momentarily, and nothing can recal it. In the views in the stereo-stand, however, we have something that will call up such pleasurable feelings at any moment, and we can gratify ourselves as long as we like. Last year we happened to be staying in a village in the most southern, or rather southeast, portion of Switzerland, and of an afternoon, for a stroll, we would take a walk into Italy and back again. Much the same sort of thing can be done at home by the fortu-

nate possessors of good collections of glass slides. They can walk into Italy for a couple of hours any afternoon they wish, without even leaving the warm fireside; and the bright transparent views they look at are not pictures of scenes they have seen, but the scenes themselves. The views do not remind you of beautiful places, so much as place you bodily on the spot, for everything is real and tangible. If the views were only a little larger, there would be nothing left to wish for, and Mr. Cook, the excursion agent, might find his travellers sensibly diminished, for there are all the pleasures of sight-seeing without any of the *desagrèments* of travelling. There is no miserable Channel passage to be undertaken, no passports to be produced, no extortionate bills to be paid. Here is the quai on the lake of Lucerne called up all at once with a turn of the handle, with a steamboat blowing off a white jet of smoke, ready to start for a trip; and as we peer into the magic peep-show, we can fancy ourselves one of the passengers hurrying on board, bound for a morning's excursion upon the bright blue waters that wash round the shores of the four forest cantons of Switzerland.

### ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

#### b. *Spectra of Alloys.*

57. The principal object of these experiments was to determine the influence which small amounts of foreign metals exercise upon the photographic image. When equal weights of the two metals are employed (tin and lead, for example, or cadmium and lead), a compound spectrum exhibiting the lines due to both metals is produced; and it is not always the more volatile metal that predominates. An alloy containing 62 parts of copper and 38 of zinc gave a spectrum in which the lines due to copper predominated considerably. In an alloy of about 2 parts zinc to 1 of cadmium the zinc-spectrum was the most strongly marked.

In another experiment, an alloy of 990 parts of fine gold and 10 of fine silver was prepared; on taking the spectrum obtained by an exposure of ten minutes, a distinct but feeble impression of the more refrangible lines due to silver was procured. A contamination of gold with silver to an extent not exceeding 1 per cent. could therefore be recognized by this means; but prolonged exposure was necessary in order to develop the lines due to silver. An analogous result was obtained when the spectrum of plumbago was taken. In this case, in addition to the atmospheric lines, the spectrum of iron was distinctly impressed; the total amount of metallic iron in the plumbago was 3.94 per cent. Graphite deposited in the gas-retorts, which contained 0.23 per cent. of iron, gave very feeble indications of iron. On the other hand, no indication of iron was observable in the spectrum of brass which contained 0.23 per cent. of iron, nor was lead indicated in brass which contained 0.7 per cent. of this metal.

58. All the foregoing spectra were obtained either from the metals in their uncombined form, or else from their alloys. The electric spectra of a few other metals which admit of being submitted to experiment in their isolated form still remain to be added. A considerable proportion of the metallic elements, however, are not included in the foregoing list. These it is almost impossible to examine, except in the form of some of their saline or other compounds. As, however, this portion of the inquiry is attended with some peculiar difficulties, I shall defer what I have to add upon this subdivision of the subject to a future occasion.

\* Continued from page 566.

§ 4.—PHOTOGRAPHIC EFFECTS OF ELECTRIC SPECTRA OF DIFFERENT METALS PRODUCED BY TRANSMITTING THE SPARKS THROUGH GASES OTHER THAN ATMOSPHERIC AIR.

59. In making experiments upon the influence of various gases upon the spectra of the electric spark, the arrangement of the apparatus was modified in the following manner:—The position of the slit, prism, lens, and camera, was the same as in the preceding experiments; but the metallic electrodes were enclosed in a stout glass tube, drilled through the side, which upon this side is ground flat in order that it may be closed air-tight by the thin plate of polished quartz. This plate is kept in its place by means of an elastic band, screwed into brass plugs for holding the electrodes. The ends of the tube are closed by brass plugs which are ground to fit the ends of the tube, and are pierced by small brass tubes for the conveyance of the gas. An elastic band, passing from one end of the glass tube to the other, keeps the brass plugs in their place. The tube is then connected with a gas-holder filled with the gas under experiment (or, when practicable, the gas is disengaged during the experiment), and, after the apparatus has been connected with the induction-coil and adjusted in its proper position, a slow current of the gas at the atmospheric pressure is transmitted, the excess of gas, as it passes out of the apparatus, being conveyed into the chimney or out of the window by a suitable arrangement of tubes.

A simpler apparatus was admissible when the wires could, like those of platinum or of iron, be soldered into glass. A piece of tubing about an inch and a half long and half an inch in internal diameter is united at each extremity to a piece of quill tubing; the wires are then soldered through its sides. A portion of the wire tube is ground away, leaving an opening to which the quartz plate can be applied, and kept in its place by small rings of caoutchouc. The gas was transmitted through the tube as in the other form of apparatus.

60. In one or other of these modes, the following gases were submitted to experiment: hydrogen, carbonic acid, carbonic oxide, olefiant gas, marsh-gas, cyanogen, sulphurous acid, sulphuretted hydrogen, ammonia, protoxide of nitrogen, nitrogen, oxygen, chlorine, and hydrochloric acid.

The general results of these experiments on the invisible rays are in harmony with those already obtained for the visible ones by MM. Angström,\* Alter,† and Plucker.‡ The conclusions at which I have arrived may be thus summed up:

i. Each gas tinges the spark of a characteristic colour; but no judgment can be formed from this colour of the kind of spectrum which the gas will furnish.

ii. In most cases, in addition to the lines peculiar to the metal used as electrodes, new and special lines characteristic of the gas, if elementary, or of its constituents, if compound, are produced. When compound gases are employed, the special lines produced are not due to the compound as a whole, but to its constituents.

iii. The lines due to the gaseous medium are continuous, not interrupted or broken into dots.

61. *Hydrogen*.—The spectrum of the spark taken in this gas is not characterized by any new lines. The most remarkable effect is the disappearance of the atmospheric lines, together with the great lowering of the photographic intensity, whether the metal employed be platinum, gold, silver, copper, iron, or zinc. It is interesting to observe that the characteristic lines of highly oxidizable metals, such as iron and zinc, are visible in hydrogen, though the impression on the plate throughout is very greatly reduced in intensity.

62. *Carbonic Acid and Carbonic Oxide*.—The lines contained in the spectra of these two gases are identical; new lines characteristic of carbon occur in addition to the lines due to the nature of the metallic electrodes. The same

lines are visible when other compounds of carbon—such as olefiant gas, marsh-gas, and cyanogen—are employed. The most characteristic lines in the spectrum of carbon are the following:—At 123 a strong line, a weaker one at 127, two strong compound lines at 133 and 140, and an intense compound line at 153.

With carbonic acid the special spectrum of silver appears much intensified. Some of the lines which appeared as dots in air are continued across the spectrum in carbonic acid. In carbonic oxide the intensity of the spectrum is less than in air; and this contrast between the two gases may be observed, whatever be the nature of the metallic electrodes.

(To be continued.)

## THE PRACTICAL PRINTER IN AMERICA.

### XV.

#### MEDALLION AND ARCH-TOP PRINTING.

THESE are very popular styles for printing from the negative, both on account of their beauty and because by their use the photographic printers are enabled to prevent defects in the negatives from printing. These are advantages which we sometimes have, and for which they are peculiarly adapted. For instance, a negative with a black velvet background is broken along the upper part of it in one place, and in another part of the plate it dried before exposing.

These defects are in such a part of the negative that a proof printed from it plain cannot be trimmed unless these defects show so much as to spoil the otherwise fine print. Such a negative, then, cannot be printed plain, and since vignetting it is not a very easy thing to do, on account of the very black background, we can most advantageously print it in either the medallion or the arch-top style.

Besides the above, there are hundreds of cases in which the use of the medallion and arch-top are indispensable.

To some the making and use of the medallion and arch-top are a source of continued trouble and vexation, and the successful photographer is very often hearing complaints from his less skilled brother photographer of his inability to make and use them satisfactorily. The reason of this is because he is careless as to what he uses in making or cutting them out, and not using them rightly after they are made.

The common card oval ferrotype mounts are very often used by some photographers in the making of the medallion and mask.

Some use a knife and cut around on the inside of the mount, but as the soft cardboard is very readily made nicky, and thus gives this nicky appearance to the cut-out, this way of making them is not advisable.

In the place of using a knife and cutting around on the inside of the mount, some place this mount on a piece of sensitive plain paper, and print the inside of it quite dark, thus leaving the unexposed part of the paper white.

After cutting a little on the circumference of the dark inside with a sharp knife, the rest of the mask is carefully cut from the medallion with a pair of shears, the point of which is pressed through the aperture made by the knife. The cutting of the medallion and mask in this manner requires a very steady hand to have the result of your labour worth using.

In making the medallion, or arch-top, I have always used brass mats of different sizes. These mats or guides are perfectly even and true, and are made of metal, so as to permit the knife being used around the inside, without any material damage to it, if only ordinary care is exercised in its use. The "cut-outs" are made of different sizes.

The regular size for ordinary card work, when the head is not the so-called "Berlin," should be 2 by 2½ inches oval. A size smaller is used when we do not wish to show as much as in the other; size, 1½ by 2½.

\* Pogg. Ann., 1855, xciv., 141.

† Pogg. Ann., 1859, cvii., 497.

‡ Milliman's Journal, 1855, xix., 213.

A size very much used for small heads is  $1\frac{3}{8}$  by  $1\frac{3}{4}$ .

One of the most convenient of all of the different sizes is  $\frac{7}{8}$  by  $1\frac{1}{4}$ . It is most excellent for the purpose of printing negatives of babies taken sitting in their mothers' lap.

A *carte arch-top*, size about  $1\frac{1}{8}$  by  $2\frac{3}{8}$  inches, is about the only size or style arch-top that is used for the *carte-de-visite*, and for other sizes your taste will dictate.

Common yellow envelope-paper is best to make these medallion and arch-top cut-outs of, as this paper utterly excludes all light that will discolour the sensitive paper. If you prefer to use sensitive paper that is not fit for printing purposes, always use the *plain* and not the albumen paper, because the latter will curl up considerably, so much so as to make it very troublesome to handle.

When you have selected your paper, and have laid it on a glass, then place your brass mats on the paper, and with a sharp knife cut a *quick, clean*, and *even* cut around the opening on the inside, leaving sufficient paper on all sides of the mats for the purpose of masking the sensitive paper in printing the different sizes, such as the *carte-de-visite*, *Victoria*, *Imperial*, or larger sizes, as the case may be.

In cutting the last part of the medallion or arch-top, considerable care should be given to see that the knife enters in at exactly the place where you first commenced to cut, because often at this part of the cutting there is apt to be a nick in the cut-out if it is not carefully guarded against.

The cutting out of these medallions and arch-tops may probably be very difficult at the first few attempts of the beginner, but if he perseveres he will find that a little practice will soon enable him to do it successfully.

*Every mask or inside will fit its own medallion or outside (i.e., the one that it was cut out of) better than it will any other one, and if the printer will remember this, I do not think he will ever meet with anything but good results.*

When the cut-outs are cut, and *before they are moved*, they should be marked in such a way that the printer can find the mask that was cut out of any particular medallion at will, for this is *absolutely necessary* if he wishes to obtain beautifully shaded lines on his prints.

The way I always do this is to mark on one end of the medallion H, which means the head of it, and directly under it some name by means of which I can easily tell it from the others of the same size. On the *same end* of the mask, and on the *same side* of the paper, we also mark H, and directly under this the name which was written on the outside from which the mask was cut.

To explain more understandingly what I mean, let us suppose that we have finished cutting a medallion and mask, and that they lay before us just as cut.

Now, on the upper part of the outside we will mark H, and directly under it, and also on the outside, "Heathen Chinees." Now, also, on the upper part of the mask we mark H, and under this "Heathen Chinees."

I will remark, here, that it is very essential to have the marks on the *same side* of the paper, and also at the *top* of each. The importance of this will readily be seen further on, when the crescent line is to be shaded on the print.

I spoke above about care being exercised in making cut-outs; that the knife enters in at exactly the place where you first commenced to cut, because often at this part of the cutting there is apt to be a nick in the cut-out if you are not careful to avoid it.

In laying the outside on the negative to print from, *always lay the side marked H up, and close to the negative, leaving the unmarked side of the paper for the sensitive paper to come in contact with.*

In laying them on considerable care and judgment should be exercised, so as to give a proper balance to the position and proportion to the print.

The principal faults that occur in laying these medallions and arch-tops on the negative for printing are:—

1st. The head is apt to be too high up, or too low down, in the medallion or arch-top.

2nd. The body looks as though it was either falling backwards, forwards, or sideways.

The nose or the mouth, as a general thing, should be in the centre of the opening, although this is, of course, open to exceptions.

To avoid the necessity of having to place the medallion on the negative for every print, I stick the corners on the negative by means of a very little of a thin solution of gum-water. I use it thin, so that it will readily come off when you wish it, but will adhere to the negative without any trouble or danger of slipping while the boards are being filled. In case it does not come off, dampen the place a little with your tongue.

In sticking the medallion on to the negative, only stick it by the *extreme tips of the two upper corners.*

Now, a print having been printed in the medallion, which we will suppose to have been the *Heathen Chinees*, we will proceed to shade the crescent line on it.

Take a nice piece of glass of suitable size, care being taken that it has no bad bubbles in it, and lay the *marked* side of the mask on it, after having previously wet the *centre* of it with a little gum. The drying should not be hurried up over a flame unless the paper with the glass is *under pressure* in the printing-frame, because it is not apt to dry *smoothly* unless it is done in that manner.

The air-bubbles between the surface of the paper and that of the glass should be rubbed away with the finger before drying. In laying the gum-water on the paper, do not touch a place larger than the nail of a little finger.

When the gum on the paper is dry, the glass should be cleaned on both sides, and then laid on the print that is to have the line shaded on it; the whole of which is then to be laid on a flat printing-frame.

There is considerable difference of opinion as to which side of the print the line is to be shaded, but the majority of photographers agree that it ought to be on the side of the darkest part of the face, so as to give brilliancy and vigour to the print on account of the contrast.

The size of this line varies according to the intended size of the finished print.

Avoid *large lines* on *cartes-de-visite* prints.

On large prints, such as 11 by 14, &c., a proportionately large line is wanted, and when done nicely the effect is really beautiful. The size of the line on these prints, 11 by 14, should not be more than one-fifth, or less than one-tenth, of an inch wide at the widest part. For 14 by 18 the size should vary from one-fifth to one-fourth of an inch wide at the widest part. For cabinet cards the size of the line should be about one-twentieth of an inch; and for the small cards the size should be about one-thirty-second of an inch wide.

Having determined as to which side of the print the line should be, the *exact place* on the side is governed by the direction the light falls on the face, and which is only ascertained by the *studying* of the negative or print.

The way I should advise the beginner to shade the crescent line is as follows:—

Lay the inside or mask on the print so that it will cover exactly every part of the printed picture, leaving only the white outside exposed, which, if you were to imagine the medallion or arch-top to be laid exactly on the print as it was in printing it, you will see that the *mask lies exactly in its own medallion or arch-top*, as it did when it was cut, and, consequently, a splendid and true line can be obtained. In laying the mask on the print, always have the end marked H up to the head of the print, since the end marked H of the outside or medallion was placed at the head part of the negative in printing the print.

Always bear the above remark in mind, and considerable annoyance in printing these styles of prints can be saved.

Now, as you have the mask fitted exactly on the print, try in *one* move to place the mask over in the direction you have decided upon having the crescent line appear.

In moving this over there will be a dark line on the other side of the print, which should, in all cases, be *exactly as large as the intended white line. Bear this in mind.*

The reason why you should be careful and have the mask placed over in the right direction in one move is, because you will be more apt to have *both lines alike*, which, if the mask lay in a different direction from what the outside did in the printing, the result will not be so good. *It is for this reason that I have advised the beginner to have his mask fit the print before he moves it to shade the line, and also to move it in one move, as this will give the desired result without fail.*

The required shade in printing the border of the print is ascertained by looking at the background, and then permitting it to darken as *near half-way between white and the tone of the background* as you can judge. Many photographers prefer to have it tinted very slightly.

If the background is *very light*, then print the outside black.

*In shading the print, never let the background and the border be of the same shade, for it will make the print appear flat and feeble.* Failures in this direction are as common in medalion printing as bad and irregular lines, and a printer who does not take care to prevent the one, rarely does the other, for they generally go together.

I do not give the above as anything *entirely new*, but, judging from the very bad, irregularly-shaped medallions and arch-tops that are too often seen, I think it could be adopted by many with profit.

#### WHAT I KNOW ABOUT "TEARS."

BY J. R. TANKERSLY.\*

It is well known to most, if not all, photographers of experience that different brands of albumen paper require different degrees of strength for the silver bath in order to produce the best results; but there are a few who perhaps do not, and to them I would say, some brands will dry smooth, and yield beautiful prints, while another brand, silvered on the same bath, will be unfit for use, in some cases drying with innumerable spots or "tears" upon it, and in other cases drying smoothy, but producing prints that have no life or brilliancy. But change the strength of the bath, and the paper which was worthless before will now give the most satisfactory results. In my own experience I have found that there will rarely if ever be "tears" upon the paper unless the silver solution is too strong. I have never known a single instance where "tears" appeared upon the paper, however bad they may have been, that would not be immediately and entirely prevented by reducing the strength of the bath.

When getting a new brand of paper, or one that we are not accustomed to working, I think it highly important to ascertain by experiment what strength of silver solution will produce the best and most satisfactory results in our own hands, and then keep it at that strength.

Some photographers attempt to work all kinds of paper on one kind of bath, and, of course, make sad failures; yet still stick to it because Mr. So-and-so recommends that particular strength. Others—and I fear their name is legion—will prepare a bath, and never test it again while it lasts, which is certainly a very grave mistake, if not gross carelessness. The bath should be tested frequently, and in very warm weather every time it is used, for the reason that evaporation is constantly going on, and in the hot weather of the summer much more rapidly than many suppose, often showing perceptible difference in a single day; and if it should have been up to the maximum strength, one day's evaporation would disarrange it, and cause loss of time and material, and possibly some impatience, for I believe we are not all saints; hence, there is a great necessity for the frequent use of the hydrometer, as guessing will not answer

it you desire accuracy, and that is certainly very essential to one's success in anything pertaining to our profession. I do not think any one can lay down a special rule in photography that will work alike in all hands; but we can give our methods for doing things, which will enable others to test them, after which each one can be his own judge as to what suits him best. I generally get the most satisfactory results from a printing bath of about forty grains in warm weather, and from fifty to sixty in winter, for Hovey's paper; and for the "extra brilliant," thirty-five to forty in summer, and from forty-five to fifty in winter—these being the brands most generally used in our establishment. Float from two to four minutes, according to the intensity of the negatives you are going to print from, always using that silvered the longest time for the thinnest negatives, and *vice versa*. Fume from ten to fifteen minutes. Fume longest for the strongest silvered paper. When making a large print in very hot or damp weather, I prefer to fume only a part of the paper at one time, as it is much more liable to discolour after fuming than before.

#### ON FOCUSING.\*

To focus sharply appears at first sight to be so simple and easy an operation that it is scarcely necessary to waste many words over the matter. Nevertheless, so many mistakes happen in conducting the operation (commercial photographs prove this abundantly) that some remarks upon the subject are not altogether out of place.

When it is a question of portraiture, the obtaining of a sharply focussed image is comparatively an easy affair, supposing we have to do with lenses of short focus and of wide angle. The slightest motion of the ground-glass brings about blurring to a considerable degree, and this circumstance helps us greatly in getting the focus. It is, however, somewhat difficult to spread the focus equally over the face and hands, and garments, and background, so that nothing is too much out of focus. As regards the degree of sharpness that an image must possess, views are very different. Some photographers focus very sharply, while others, again, err from throwing their models too much out of focus; and it must be admitted that there are portraits to be seen which, as regards focussing, leave much to be desired, and are yet of a wonderfully artistic nature. In this category may be put some of Adam Salomon's admirable pictures.

Much more difficult is the focussing of landscapes, and more difficult still that of reproductions, where very great accuracy is desirable. Generally, a matt glass plate is employed for focussing, which, if it is to fulfil its object thoroughly, should occupy the same plane exactly as the plate in the dark slide. As a rule, the proper position is determined by the aid of a rule, which is pushed through the opening left by the lens. If, in this case, the distance of the focussing screen and that of a glass plate in the dark slide is, in both cases, identically the same, then there is no difference to be feared. But those who have tried this plan two or three times will soon find that it is very easy to make a mistake of a millimetre, and for this reason the plan cannot be relied upon. The best test is that suggested by Dallmeyer, which consists in putting a piece of matt glass into the dark slide, and inspecting the sharpness of focus in this way. A portrait lens is the best instrument for testing with, while the object should be some coarse printing affixed to a drawing board. It is often the case that one has not a plate of ground glass at one's disposal; in this case a sensitized and washed iodide plate will answer the purpose. If you work quickly, indeed, an ordinary glass plate, upon the inner surface of which you have breathed, will do very well. It is necessary, however, that in focussing in this way a magnifier should be used, of which mention is made further on.

\* *Western Photographic News.*

\* *Photographische Mittheilungen.*

When the point of sharpest focus has been decided on, the dark slide is removed, and the focussing screen put into the camera instead. If the picture is still sharply reflected on the latter, there is no difference in the distance of these two planes from the lens. If there is any difference, however, this can easily be ascertained by pushing the focussing screen backwards and forwards, and then the dark slide can be corrected.

Of as much importance as the operation of focussing is the grain of the ground glass. It is singular that notwithstanding many complaints about the matter, a matt sheet of glass with very fine grain is seldom met with. But a very short time ago we received an excellent camera from one of the most celebrated firms, the focussing screen of which was worth nothing at all. Under such circumstances there is nothing to be done but to produce a fine matt surface oneself, and this is done by rubbing a few drops of olive oil upon the ground glass. At first the latter becomes quite transparent from such treatment, but by rubbing with blotting paper the superfluous oil is removed, and every degree of fineness may be secured. For very fine subjects a certain amount of transparency is very desirable, although it is necessary to be very careful when using the magnifier.

The magnifier is an exceedingly useful aid for focussing sharply; it is very generally used, but seldom in the proper way. Every photographic magnifier may be drawn out and pushed in, and is thus adapted for long- and short-sighted people. This adaptation of the instrument is often forgotten. When working with a coarse glass plate in the ordinary way it does not matter much, but with finer work it is a question of importance. To adjust a magnifier properly, a pencil mark is made upon the rough side of the focussing screen with a finely pointed pencil, and this is looked at from the other side of the glass, pushing in the instrument until the greatest amount of sharpness has been obtained. An experienced operator does not require a pencil mark to aid him, for the grain upon the glass is sufficient guide. When you have secured the image of the sharpest focus, the spot is marked by a stroke upon the tube of the magnifier, and in this position the latter may always be employed in obtaining the greatest sharpness in fine objects.

In very accurate work you may operate without a ground glass; instead of it an ordinary sheet of glass is taken, and on the inner side of it are made several strokes with a diamond. Then the image is so focussed that it falls sharply upon the diamond lines. This is not always practicable without a magnifier, but otherwise the work will be very accurate. The view of such a camera picture with the magnifier and without a matt glass is wonderfully sharp and full of detail. To be quite sure of your work with the magnifier, and to ascertain that the picture really does fall in with the diamond lines, it is necessary to move the head to and fro; if the picture then moves upon the lines, it is not clearly focussed. This plan of focussing is to be recommended for fine reproductions when it is a question of mathematical accuracy. Of course, in such a case, as in any other, only a portion of the picture can be focussed at a time. Dallmeyer recommends the focussing of a point midway between the centre and the margin, while Steinheil recommends focussing the centre itself in the case of reproductions.

It is different with landscapes. The enormous difference in the distance of various objects necessitates in this case very different treatment. Often there is to be found in the landscape only one principal point of interest, whether it is a ruin, a tree, or what not, and then this must of course be sharply focussed; but sometimes it is a picture of combined attractions, with foreground and distance, and then we focus not on an object close at hand, but one at some distance. The reasons for this are easily stated.

In the figure here shown, L is the lens, upon which fall

parallel rays from a distance, which are brought to a focus at  $f$ . If upon this lens there fall also rays from a nearer object, they diverge somewhat like the dotted lines, and their focus is further off at  $p$ . If the ground glass is moved to the focus  $p$  for the nearer object, then the further ones are rendered in a blurred manner, and the circle of divergence is at  $c d$ ; while if the focussing screen is put forward to  $f$ , then the nearer objects are out of focus, and the circle is at  $a b$ . Upon the size of the latter

depends the degree of blurring or unsharpness, for the smaller it is the sharper is the image. It is easy to see from the figure that  $a b$  is smaller than  $c d$ , or, in other words, the blurred character of the nearest objects when focussed at a distance is not so great as the blurred character of distant objects when the camera is focussed for new objects; if, therefore, it is a question of securing a general landscape, and not a photograph of any particular point, then it is much better to focus on a distant object than on a near one. One should not, however, take a very distant object, but one in middle distance.

#### A WORD ABOUT INTENSIFYING.

BY H. L. BINGHAM.\*

I HAVE noticed of late that much is being said on this subject of intensifying the negative, and observe that a great majority are using pyrogallic acid, and some even sulphuret of potassium and bichloride of mercury; also those who expose their plates to diffused light, and various other methods. I do not know that I can impart anything new to my photographic brethren, but this subject and its discussion has impressed me very strongly, inasmuch as I seldom, in my practice, ever strengthen a negative—in fact, often labour to reduce intensity. If required to strengthen a negative, I simply (before or after fixing, usually the former) flow my plate with some of my bath solution somewhat reduced in strength, and then develop again as usual; merely continuing the process of development in its most natural manner. By this treatment of the negative are secured most brilliant effects, and the soft roundness secured is all that can be desired.

I would suggest that every photographer try this method, and keep trying it until satisfactory results are obtained. Very much depends, in securing the best results in the chemical manipulation of our art, upon a thorough knowledge of the formulæ followed; and in this science, as in others, repeated trials are requisite to success. Very many—their name is legion—try a good formula, and reject it because they fail on the first or a few subsequent trials; but the fault is not with the formula—it is with the lack of knowledge in using it. Patience, and a careful observation of all results while testing the various methods, you may employ to compass desired ends; and, with these requisites, a great deal of hard persistent thinking and study will lead you to a higher place in your art, by giving you knowledge wrought out by your own exertions that will produce the finest results attainable, richly rewarding you in honour, and adding more substantial benefits by putting wealth in your purse.

## IVORY AND OTHER SUBSTANCES FOR PHOTOGRAPHS.

It is not a little remarkable that, remembering the number of substances or surfaces suited for pictorial representation in photography, no material but paper has ever received an extended trial for photographic purposes. In the early days of the art this was not difficult to understand, for a variety of reasons. If ivory were employed for printing on, it was difficult to sensitize, and more difficult to fix and wash perfectly. Surfaces of wood for fancy purposes were equally difficult to deal with, and prepared canvas presented similar troubles. Substitutes for ivory were invented, but they simply made matters worse. Mr. Mayall patented a substitute for ivory for photographic purposes, which, so far as yielding a delicate printing surface was concerned, was excellent, but having a gelatinous or albuminous basis, it was difficult to eliminate the hyposulphite after fixation, and impossible to dry flat, without curling and warping. The modes of transfer which now exist, whether with direct positive, taken on wet collodion process, the collodio chloride prints, or carbon prints, have changed all this, and removed the chief of the difficulties. But still paper remains supreme. For all kinds of ordinary pictures it is natural that this should be so, as no substance can compare with its suitability; but it is a little surprising that for variety sake, and for special purposes, other substances have received so little consideration.

Our attention is called to the subject by reading the specification of a patent taken some time ago, but not completed. The process for which protection was sought was a method of "Preparing Surfaces for Painting, Photographic, and other Printing;" the text is short, and runs as follows:—

"My invention is intended to provide a substitute for ivory, paper, or other materials hitherto in use for painting and printing on, in which great delicacy and evenness of surface are required. And my invention consists in the preparation of metal or other surface impervious, or nearly so, to the mixture hereinafter stated, by the application of the various kinds of wax or its compounds, white or coloured—by preference, pure sun-bleached wax—mixed by means of a carefully applied heat with a white body colour, such as flake white, white lead, zinc white, or similar substances, either pure or tinted. The said mixture is applied to the metal or other surface by heat or by other convenient means."

We fear that any results which could be obtained on the surface in question would scarcely be of sufficient value to repay the cost of even the provisional specification. Wax,

although possessing excellent qualities in its plastic character, is too easily injured to be suitable for a pictorial surface. But there are other substances with more promise, and a brief glance at some of those which have been proposed or tried may be interesting, and may possibly stimulate experimental ingenuity. Mr. Mayall's patent ivory substitute might, for instance, as he himself recently suggested, be found valuable as a basis for transferred prints, although its use was impracticable for pictures produced and fixed upon its surface. The specification of Mr. Mayall's patent contained four methods of forming artificial ivory. In the first method tablets of gelatine were first formed, and these were to be "immersed in a bath of alumina held in solution in sulphuric or acetic acid," the result being a combination between the gelatine and alumina, which gave an opaque white tablet capable of being polished and finished when dry and hard like ivory. In the second method, which seems less promising, a salt of alumina was to be mixed with gelatine, and then the tablets manufactured therefrom. In the third method, equal portions of bone or ivory dust and albumen or gelatine were to be worked into a paste, then rolled into sheets, and dried. In the fourth method, finely powdered baryta and albumen were well worked together, and then rolled into slabs and dried. The last method somewhat resembles Mr. Burgess's method of preparing eburneum; in the latter zinc white, instead of baryta white, being employed, and gelatine instead of albumen. One of the best surfaces we have seen was the invention of Mr. Griswold, of America. He prepared, by a secret process, a collodion which, whilst not differing to the eye from other collodion, gave a perfectly opaque dead white film. This, when applied to a ferrotype plate, gave a pink-white surface, even, smooth, and matt in texture, presenting an admirable ground for a photograph. Mr. Griswold is unfortunately dead, and we believe that his secret died with him.

For many purposes, papier maché, finished with a white enamel surface, is a capital substance for photographs, especially for highly finished miniatures in oil. This substance may be used either for receiving a transferred image produced by any process, or may, with less convenience, be used for printing on direct. Some years ago, whilst we were experimenting with collodio-chloride, we obtained some tablets of this kind which were specially made for us by a house in Birmingham. If a demand existed, we have little doubt that they could be produced at a very moderate price. Collodion transfers have been made to prepared canvas for oil painting, but there is room for further adoption of the idea. We have produced good results by transfer to the prepared silk, with a very fine and perfect surface, effective for plain prints, and admirable for miniatures. White oilcloth, of the kind used for table covers, forms also a useful basis for transfer for some purposes. For some ornamental purposes, white wood, of fine texture, is excellent, but has rarely been utilized. There are other similar substances which present an interesting field for experiment.

## LANDSCAPE PHOTOGRAPHY.

In a recent article in the *Photographische Notizen*, Professor Vogel concludes with some excellent advice to travelling landscape photographers, who are apt to overload themselves with all sorts of out-of-the-way articles, that are carried, not because they are necessities, but because, under exceptional circumstances, they might be wanted. He sums up his own experiences as follows:— "Although a liberal store of chemicals, &c., may be useful on a tour, it is a costly matter to go dragging a superfluous quantity of goods about with you. I have specified in my manual the quantities of material that are necessary for a certain number of plates. Thus, for forty plates measuring seven inches by nine, which I took with me to the Carpathian Mountains two or three years ago, I only

had one pound of iodised collodion, and this proved ample for the purpose. For the same surface of glass I had but one pound of protosulphate of iron, half a pound of alcohol, half a pound of acetic acid, a quarter of a pound of ether, an ounce of citric acid, and half a pound of uegative varnish.

"It is surprising how very little material is employed if you are a passable manager, and never waste your chemicals. As a matter of course, everything must be very carefully packed, and for travelling I always employ a trunk with partitions specially fitted for the purpose. Every bottle has its proper place, which is padded with felt, so that it is not necessary to pack or line with straw.

"I reduce the number of glass articles to a minimum, and never have any glass funnels, for they break before anything else; I always employ those of gutta-percha, which will keep safe and sound for years. No injurious action upon the silver bath is to be feared, for the operation of filtering takes but a very little while. As a matter of course, I always sensitize in a porcelain dish or cup; not so much silver solution is then required, and the operation is better under one's control and sight. I employ a genuine Japan utensil, not a spurious one that has been made in Europe. My tent I have often described: it is adapted for tours where no vehicle can pass, and is especially noted for its lightness and cheapness. I have the first I constructed still in my possession, after it has been employed for three years. It withstood a severe shaking in my journey among the Carpathian Mountains, and it has been borrowed two or three times, which is a far more severe test than a mountain tour; and yet it is still in a very serviceable condition."

#### THE NATURAL HISTORY OF A NITRATE BATH.

OUR Baltimore contemporary, *The Photographer's Friend*, answering a correspondent who is anxious about the cause and cure of various symptoms manifested by a negative bath in the ordinary vicissitudes of its career in the darkroom, gives the following summary of the constitution and treatment of the bath, for the most part excellent. We should except, however, the recommendation to use ammonia for neutralizing the solution, as the nitrate of ammonia formed, having the power to hold oxide of silver in solution, often tends to produce an alkaline bath.

"A bath properly made contains nitrate of silver dissolved in pure water, iodide of silver dissolved in the nitrate solution, and a slight quantity of nitric acid. The purer the water and silver, the less quantity of acid required. Acid is generally regarded as a restrainer and as an anti-fog agent, but its real use is as a solvent of the foreign matter which may get into the bath. It does not necessarily prevent fog, nor does it cause slowness of working.

"Let us make a bath in the simplest, handiest way. To 33 ozs. of water add 120 grs. of silver, 6 grs. of iodide of potass., and set in the sun for at least forty-eight hours; then add 2½ ozs. of nitrate of silver, stir well, and allow to stand four or five hours more in the sunlight; filter, and you have a pure bath to start with. Test this solution with litmus paper, and add nitric acid drop by drop until the paper turns faintly red. Your bath is now acidified. Next test your bath, to see if it is sufficiently iodized, by allowing a coated plate to rest in it ten minutes; if the collodion appears to be eaten off in lines running the same way the plate was dipped, the bath needs more iodide of silver, which make and add in this way: take 10 grs. of silver and dissolve in 1 oz. of water in a separate glass, dissolve 10 grs. of iodide of potass., and throw these two solutions together in the dark; allow the yellow precipitate formed to settle, pour off the water and fill up the glass with fresh water, settling and pouring off as before; do this three or four times, drain the precipitate as dry as possible, and add to your bath and allow to stand over night, always in the dark; filter when it is ready for use.

"When a plate is dipped in a silver bath the object is to obtain a coating of bromo-iodide of silver, which is formed by the silver in the bath uniting with the bromides and iodides in the collodion. In this operation the bath loses some of its silver, and the collodion part of its alcohol, ether, bromine, and iodine. A certain quantity of these chemicals in a bath is necessary for its perfect working, but after many plates are dipped the bath becomes weak in silver, and saturated with ether, alcohol, and iodine.

"That the bath is weak may be known by the length of time required to coat a plate; that it is saturated with alcohol, by the difficulty in coating it perfectly, the greasy lines refusing to disappear; and excess of iodine is shown by a sand-like deposit over the plate when brought from the bath, which causes, when developed and fixed, small black pinholes.

"To rectify a bath showing either of the above troubles, drop ammonia carefully into it until just neutral—that is, will not turn blue litmus red, or red litmus blue; set this in the sun until it blackens and clears again; put them in your evaporating dish and boil slowly down to about one-half the bulk; now add pure water—that is, such as has been treated as first described, which must always be kept on hand, until the hydrometer indicates the right strength, 45 grs.; filter the solution, make slightly acid again, and it is in good working order. Should you require more solution than this doctored bath will give, do not add silver to it, but add new bath made as first directed.

"When a bath is too acid, neutralize carefully with ammonia, exercising great care not to overdose; when too alkaline, add acid carefully. A bath too acid produces opaque spots like dirt over the negative or ambrotype, spots more intense than the rest. When alkaline, the plate will have a greyish dust or fog over it, which can be rubbed off with the finger.

"Now for a few difficulties frequently blamed upon the bath. Dirty plates producing fog, light leaking into darkroom, camera or holder producing fog, undertime and overtime (both fog producers), old developer with too little acid, dirty fingers, dirty corners to the holders, and dirt everywhere—all first-class foggists. Streaks come from drying the plate too long or not enough, from stopping the plate in bath before it is covered with solution, insufficient coating, too strong developer, and careless flowing of same. Spots come from dirt not filtered out of bath, collodion, or developer, and from dusty, unclean rooms."

#### TRANSIT OF VENUS: PREPARATIONS FOR OBSERVATION.

BY CAPTAIN ABNEY, R.E., F.C.S.

*Thebes, November 11th.*

ACCORDING to promise, I send you a few lines regarding our work up the Nile.

It is evening, and we have only just arrived at our destination, so can hardly say what sort of prospect is before us for photographic operations, though, if it be a climate and country like that through which we have lately passed, it will be simply magnificent. Owing to the kindness of the Khedive, we have been towed up the Nile by a Government steamer; and when I say "we," I mean self and three Sappers, and our boat, or *dahabeah*, as it is called. The voyage has been very slow, and has taken us thirteen days to accomplish, as we went barely three and a-half miles an hour up the stream; and owing to Colonel Campbell (an amateur who is to observe the transit also at Thebes) taking advantage of the steamer to get his boat towed up as well, we have taken longer than we otherwise should have done. On the whole, however, it has been pleasant enough, and we have turned one of the cabins into a dark room. This enabled us to take instantaneous shots at the objects of interest on the banks, which have turned out most successfully. I have been using a small 4¼-inch square camera (with square

plates) for the purpose, and with one of Dallmeyer's 6-inch doublet stereo lenses have got pictures which I little hoped to secure. The first hundred and fifty miles was very destitute of interest, the banks were so flat; but since then the scenery has been very beautiful, the hills on each bank sometimes taking most picturesque forms, and with the palms, storks, and natives in the foreground, have made very pretty little bits, which will be interesting as reminiscences. The light is simply perfect for photography, so very actinic. In our spring, exposures of half-a-minute would here be reduced, I think, to about five seconds. Twice on the voyage we have stopped to land and take objects of interest; once at Siout, where we scaled the hills to photograph the old wolf mummy caves and the rock-cut tomb Stabl Antar. We here found that the bath was likely to give trouble through pinholes, and, in fact, that the negatives were never quite free from them. We also found that for most subjects a fifteen-grain iron was sufficient; a thirty-grain was inclined to give flatness. This is a peculiarity I never encountered in India. In fact, there I have frequently used fifty-grain to avoid "chalk." Here the shadows are so transparent, never very deep, and quite bright with detail—very different to all other Eastern countries I have been in. I lay this to the peculiar whiteness of the surroundings, which reflect the light into the deep shades. An interior of a cave which I should have given twenty minutes to in England, I found was enough exposed with but three minutes. It is very hot working, though the north wind which we have keeps a certain amount of freshness in the air. It is very dry, the difference between the wet and dry bulb thermometers sometimes being as much as 10°; 85° is what the former registers in the shade. The Nile water itself is only 73°. This brings me to talk of the water. In appearance it is a dark chocolate colour, which disappears when allowed to settle, or when filtered through porous earthenware. Trying to make a bath with the water thus freed from sediment was not a success. In the sun it immediately turned brown, and never quite recovered its colour again. Plates sensitized with it were foggy, and none of the usual remedies answered. There seems literally no chloride in it, but a fair quantity of nitrate of soda (the complete analysis I have not yet made). It is very soft, and a lather is made immediately in it. It is capital to drink when you get used to it, but hardly refreshing. For washing off developers, and so on, it is capital, but one always requires a final dose of filtered water to free a plate from the sediment.

A bath thirty grains strong is most satisfactory, inattains disappearing almost entirely, even with long exposures. On looking over my chemicals the other day, I discovered that, inexplicably, the sulphate of iron was likely to run short, as also the glacial acetic acid. I was at my wits' end. At length it struck me, in passing through a village, and seeing them dyeing, that they must use the former, so I sent out a pattern to the bazaar. In return I got about three pounds of the protosulphate (rather decomposed, but quite usable), and at the very reasonable rate of eightpence a pound. I found my dragoman had got a large stock of white vinegar, and this I have impressed into the service in lieu of the acetic acid; so now I am in great plenitude. I anticipate great days at Karnak and Luxor. I expect to have some hundreds of views by the time I leave; and if fate wills it so, a few will be up at Assouan, near the first cataract, and Philoe.

I don't know what Mr. Bedford thought of the Nile, or if he was hurried through it by circumstances. To my mind, what I have seen of it gives greater photographic promise than any country I have yet seen. I have carefully gone over Frith's and Sebah's photographs, and am confident that not a tenth of important views are published. There seem to be a great many gaps which want filling up in them. I shall try and help in the good

work. Many things are changing, many getting more delapidated and defaced. Hence it behoves the black art gentlemen to look sharp with their cameras, and register aught that may be of interest, and which may have vanished in the next few years.

## A PHOTOGRAPHER'S EXPERIENCES IN THE LIBYAN DESERT.

BY PHILIPP REMELÉ.

[We have already mentioned the fact that M. Remelé, a Berlin photographer of reputation, formed one of the African exploring party sent, with the sanction of the German Government, under the command of the well-known traveller, Gerhard Rohlfs. We are now enabled to place in the hands of our readers M. Remelé's diary, which he has sent home to Dr. Vogel, the President of the Berlin Society for Advancement of Photography, for publication.—ED. P.N.]

LAST summer I was requested by M. Rohlfs to take part in an expedition into Africa, which was to proceed into the interior under orders of the Viceroy of Egypt. My duties were to be those of photographer to the party. The expedition left Europe in November, so I had plenty of time to get an outfit together. As the expedition took place in the winter, and I had read that at that time of the year the temperature was not a very tropical one, I determined to make the same arrangements which I had used for several years past in Germany, without effecting any radical alterations in my plan of operating. My travelling tent and equipment are sufficiently described in my work on landscape photography; it is only necessary for me to mention, therefore, that I provided, in most cases, a duplicate set of apparatus and utensils, to be proof against accidents, &c. Dark slides, baths, dippers, dusting brushes, &c., were all provided for in duplicate. A box with all kinds of handy tools for effecting repairs was not forgotten.

Before the outfit was packed and sent off, everything was thoroughly inspected. I might, had I wished, have purchased new apparatus throughout at the expense of Government; but I preferred to employ my own, which I had worked with for some five years, and which was still in perfectly good order, and well seasoned to the weather. Splitting or warping of the wood was not to be feared, I thought, and the issue of affairs has proved my assumptions to be correct. My whole apparatus consisted of the laboratory box, with necessary utensils, a bundle consisting of tent and stand, three boxes with glass plates, and a small case with reserve articles and chemicals. The bottles were packed in straw, and put into pigeon-holes in this condition, so that any one could be taken out and put back again in a very short time. No breakage occurred in this package, although it was not always very delicately handled. All the chemicals were of the purest and soundest character.

I employed the new folding camera of Meagher. For large pictures, 8 by 6 inch, I used Steinheil's aplanatic 14-inch, as also Busch's 15 by 19; for the stereoscopic plates, Busch's 24-inch lens. The Pantascope was not employed, for it was never required.

I used, as on former occasions, Beyrich's instantaneous collodion, with iodizing solution separate, and was quite content with its work. That now and then difficulties arose was only to be expected, when the nature of my work is taken into consideration. Of these I will make mention further on. I employed the usual solutions; the silver bath was of in one twelve strength, and when necessary a few drops of glacial acetic acid were added. For developing and intensifying I employed the double sulphate of iron and ammonia, on account of its preserving qualities; for fixing, cyanide was used. In favourable weather I varnished the negatives in the sun, otherwise in the tent over a spirit lamp.

When the members of the expedition met together in Alexandria, the whole of the baggage was put in the railway and sent to Minich. From Minich we went by steamer up the Nile as far as Siut. On the journey, which lasted many days, I could do nothing, because I found it impossible to get at my trunks in the mass of packages, but at Siut the unpacking began. Everything was in good order, with the exception of one case in which my portable laboratory was contained, and which I had packed with extra care. It seemed as if the silver solution had run out in several places; and this proved to be the case, one bottle of silver solution and another of iron having become broken. I had plenty to do to put everything straight again, but there was opportunity afforded me, fortunately, for the fitting out of the caravan took up a week.

Round about Siut were some very fine bits of country, and as the weather was favourable, I took the opportunity of taking a few good negatives, there being no difficulties, beyond the dust, to be encountered.

On the 17th December the caravan was ready. That evening we pitched our tents upon a broad sandy plain behind the burying ground at Siut, the usual camping ground of caravans proceeding to Central Africa, and here we passed our first bivouac. The camping arrangements made by M. Rohlfs were exceedingly practical. The tents obtained from Paris were light, and yet very firm and solid, quite competent to resist the effects of a strong wind. In the interior were a camp bed, and table and chair—everything made to pack closely. The tent of M. Rohlfs was larger than the others, and had room enough for all five members of the expedition to sup together.

The next morning, it was a long time before we were ready to start. Irrespective of the many difficulties connected with the Arabian camel drivers, the loading of the camels with boxes and cases of all sorts and sizes, and the inaptitude of our black servants to the job, occasioned great delay. My photographic case was too heavy, and had to be lightened. At last, at about half-past ten, we made a start. Of course on the first day, and for some little time afterwards, matters scarcely went on so smoothly as was desirable. Many of the camels, who were not properly loaded, threw off their burdens, some shied, and now and then one of us Europeans, who were not used to the new mode of conveyance, lost his seat and came tumbling down into the sand. I did not mind the last difficulty, but the throwing down of the cases caused me much anxiety. Only once, however, was a package of mine thrown down in this manner. This one, however, came utterly to grief, and of two hundred plates contained therein, only seventy-nine were recovered whole. The latter—they were of the larger size—lasted exactly until our return to the Nile. It was impossible to photograph during the march of the caravan. As to bringing it to a standstill, that could not be entertained for a moment; and as to keeping my camel back, unpacking the utensils, and setting up tent, &c., and afterwards catching up the rest of the party—such a thing was impracticable. Of an evening after arrival, and in the morning before starting, there was no time for camera work. But for all that, I do not think I missed many points of importance. The desert photographs I collected were taken during excursions made from some oasis. It was precisely in the neighbourhood of these spots, where you descended from the sandy plateau into the green oasis, that the finest landscape views were to be met with, for on the sandy plains there is very little to be found of interest.

Of the desert through which we travelled, bereft of every trace of vegetation, and presenting nothing to the eye but a vast wilderness of sand, I need say nothing, as the scene has often been minutely described.

After travelling for twelve days over these sandy plains, we sighted at last, on the 30th December, at ten o'clock in the morning, Farafrah, the smallest oasis in the Libyan desert, our first goal. The village seemed to be only a

few miles distant, but the clear transparent atmosphere of the desert is very delusive as regards distances, and it was not until four o'clock that we reached the spot. The inhabitants, who had not been advised of our coming, were greatly astonished at our big caravan of ninety camels. They hardly believed in a friendly manner, and demanded high prices for the food we had to purchase.

My first excursion was to the garden of Farafrah. I must admit that I never dreamed of beholding such luxuriant vegetation. It was very easy to institute a number of interesting excursions. As the caravan remained here only a couple of days, I had to look out for still moments, and my anxiety on this account caused me to wander forth at night time to beat at my destination at a favourable moment at daybreak. Our camp brought together a number of jackals, which, when everything was still, ventured very close to our tents; the least noise, however, frightened them, and I could never get near enough for a shot.

In very still weather the thermometer stood at freezing point at daybreak; but by eight o'clock the sun had so warmed the air that my tent could be thrown open in the garden. The foliage was very thick, and the sun could scarce penetrate it except at certain points. My first exposure required ten minutes; the others, according to object and illumination, one to five minutes. At first the chemicals worked well, but later I had many difficulties to contend with. Sometimes I had to go a great distance with the plates, and during my journey the temperature would rise considerably; and for this reason, as also because I had frequently to wait for still moments, my plates became covered with dry patches, and sometimes fogged.

As I could not always be near my apparatus, the villagers were given to playing me all sorts of pranks, either out of curiosity or ill-will—I suspect the latter. They would unscrew my camera, or move it away from its position. All these things were naturally very annoying; but, as a rule, when I came to finish my work of a night, I was usually satisfied with it.

(To be continued.)

## Correspondence.

### LIFE-SIZE PORTRAITS.

SIR,—In a leading article in your issue of last week, I find the following sentences:—

“In the Crawshay Competition, incentive was offered to the production of a class of work of a very unusual—we might almost say of an unknown—kind. So far as we know, life-sized heads produced direct in the camera had never been attempted, certainly never exhibited before.”

“Mr. Crawshay had himself made some effort in that direction with sufficient success to make him wish to see what more could be done when a number of men made special effort.”

The following two letters will show you that you have overlooked my work, seeing that the life-sized head therein alluded to was exhibited with two others in the Society's Exhibition in 1870. Though not so fortunate as to have attracted your notice, it was from seeing it at that Exhibition that the editor of the *Art Journal* was moved to ask me for a copy of it, and perhaps you will now modify your statement that “life-sized heads produced direct in the camera had never been attempted, certainly never exhibited before.”

Copy of letter from E. M. Ward, Esq., R.A., to Colonel Stuart Wortley.

Kent Villa, Lansdowne Road, Kensington Park, 29th Nov., 1874:

DEAR COLONEL WORTLEY,—I quite sympathize with you in your objection to the statement you mention as having appeared in the PHOTOGRAPHIC NEWS, that life-sized photographic heads have

only originated since the last two years;\* the very circumstance being contradicted by the fact that I have on my walls one of the most beautiful specimens of that kind, of a member of my family, executed by you four years since, and which I value equally for the faithfulness of its resemblance as for its great merits as a work of art, which are, in my estimation, of a high order.—Very truly yours,  
(Signed) E. M. WARD.  
Colonel Stuart Wortley.

*Copy of letter from S. C. Hall, Esq., Editor of the Art Journal, to Colonel Stuart Wortley.*

Avenue Villi, 50, Holland Street, Kensington, W., Dec. 1, 1874.

MY DEAR SIR,—There is hanging in Mrs. Hall's boudoir a most beautiful photograph, life-size, of her god-daughter, which you gave to her in 1870. It is a very perfect example of the art. There has been nothing more perfect produced, to my thinking, since 1870.—Most truly yours,  
(Signed) S. C. HALL.

With respect to the concluding sentence quoted by me from your article, I take the liberty of mentioning the following facts:

The pictures alluded to were taken with a particularly fine lens of Mr. Dallmeyer's make, and they appear to have attracted Mr. Crawshaw's attention, for shortly after the Exhibition Mr. Dallmeyer wrote to me asking for some copies of my pictures for him to send to Mr. Crawshaw at that gentleman's request. These copies were furnished to Mr. Dallmeyer, and I think I am therefore justified in assuming that the exhibition by myself of life-size heads in 1870 was the starting point of the Crawshaw competition; and I trust that the evidence I have laid before you will make you think the same. You will not forget that the Crawshaw competitions were in 1873-74, and that my life-size heads preceded them by three years.—Yours, &c.,  
H. STUART WORTLEY.

[We willingly rectify the statement doing Col. Wortley some injustice, and in reparation insert, at his request, the letters which confirm his claim, although his own statement might have been sufficient. At the moment of our writing we had forgotten the heads in question. The fact that they were not quite life-size, as we find on reference to our notice of the Exhibition of 1870, and that they were rather subject pictures than portraits, to some extent explains their absence from our memory in connection with life-size portraits. They were, however, very noble pictures, taken direct in the camera on 24 by 18 plates, the art qualities and photographic excellence of which we were enabled to speak in the highest terms at the time; and it is not at all improbable, as Col. Wortley suggests, that they had influence in initiating Mr. Crawshaw's interest in such pictures, which culminated in the very important competitions of the last two years.—Ed.]

#### KENNETT'S GELATINE PELLICLE.

SIR,—On the 5th June last there appeared in the *News* a letter from Mr. Aldridge speaking in high praise of Mr. Kennett's pellicle, and in which letter he stated that (at that date) nearly three hundred photographers had been supplied with the preparation. On the 19th of the same month you gave us a very interesting article on the same subject.

Being thus fortified, I wrote to Mr. Kennett for a supply of his pellicle, which I received, and duly tried; and in communicating to you the result of that trial, on the 3rd July, under the signature of "A Dry Plate," I asked if some of the three hundred gentlemen referred to would give us their experiences with this new compound. In reply to my request, "J. R.," on the 10th July, stated that he had encountered similar difficulty to my own; and, on the 17th, "W. J. C. M.," to a large extent confirmed my statements; and these are the only gentlemen who have responded to my letter. Mr. Kennett set "W. J. C. M." right on a point or two of detail on the 24th, and I think I

am correct when I say that not one word has appeared in the *News* of any practical value from that date until the 6th instant—a period of four months—when "A Portrait Painter" simply confirms my original statement as regards sensitiveness.

Now, sir, as three hundred persons had had this pellicle issued to them before the 5th June, we may assume that double that number have tried it during the summer months; and it does seem strange that out of so large a number of experimentalists there has not been found one to sing the praises of this pellicle, save and except this same Mr. Aldridge, who introduced it to us six months ago, and who now, on the 20th instant, comes forward and simply recommends Mr. Kennett to charge four times as much for it as he does at present. If Mr. Kennett should be so ill-advised as to put a prohibitive price upon his pellicle, that will be his own affair; but is it not too early to ask the public to pay this exorbitant charge for a preparation the results of trials with which have only been given by less than half a dozen persons, and which results, in nearly every case, have been of an adverse character?

If this gelatine pellicle be really a good thing, Mr. K. will not need to increase, but rather to decrease, the cost of it; because the absence of collodion and silver bath, with all their attendant difficulties, will be so great a boon as to induce, at all events, the large body of amateurs to adopt it in preference to the usual materials used in photography. I therefore ask again for information, both for Mr. Kennett's benefit, as well as for that of the profession and of the amateur.—I am, sir, your obedient servant,

A DRY PLATE.

SIR,—"A Worker's" letter in your issue of 27th instant would perhaps carry more weight if more explicit. He brings a very vague charge against Mr. Kennett's gelatine pellicle, based upon some undefined notion of the idea having been borrowed from other workers in emulsion. This savours more of the antipathy of a rival manufacturer than the disappointment of an impartial experimentalist.

If the idea has been pirated, how does "A Worker" get over the fact of its greater rapidity than that of any other dry process? I have been able to give Mr. Kennett's pellicle but a short trial, and, though met by many difficulties in the shape of coating my plates, I have no hesitation in stating my belief that it is by far the most rapid process in existence. Mr. Kennett's only mistake, in my judgment, is, that he does not sell "dry plates," instead of an emulsion.

The testimony of some of the members of the Liverpool Amateur Photographic Association has already been emphatically declared in favour of this desideratum.—Yours faithfully,  
S. S. YOUNG.

*Fairmile, Cobham, Surrey, Nov. 30th.*

SIR,—In justice, I am sure you will allow me space to answer a letter signed "A Worker," published in your last issue. His epistle was in answer to one written by Mr. Aldridge.

To the first part of "A Worker's" letter I quite agree in thinking Mr. Aldridge's letter a little out of place. I thank Mr. Aldridge, nevertheless, for doubtless he did it with a kindly motive. The rest of "A Worker's" letter, I beg to say, is a series of misstatements from beginning to end—whether wilfully, or not, I leave to himself and your readers to judge. As he has made such a positive assertion that I am indebted to others for the process—or, as he puts it, for the emulsion—I now ask him to name, for the information of your readers, as well as myself, who those others are, that I may do them ample justice, and acknowledge my indebtedness to them. No one hitherto has accused me of stealing their brains for my own benefit, as he calls it. Perhaps "A Worker" wishes to put in a claim himself! If so, let him come forward boldly, and state his name. No,

\* Mr. Ward misunderstands our statement. We saw life-size heads by Mr. Crawshaw in 1871.—Ed.

that can scarcely be, as "A Worker" would hardly deign to discover anything of so worthless a character; for such, in the eyes of "A Worker," it must be, it being of no benefit to photographers, amateurs or professionals.

It would have been in much better taste had he spoken for himself only, and not taken on himself to pass a verdict for the opinions of thousands. It so happens that I have in my possession numberless letters from all parts of the country, giving his assertions direct contradiction, and in which I am thanked for having placed in their hands, as they say, a process which is a saving of money, labour, time, and health.

I herewith enclose two prints taken by Mr. Willis, of Scarborough, on the 5th instant, and on plates prepared with this "worthless" process. I wish you, as an impartial judge, to pass judgment on them, and say what is your opinion of a process that will produce such work at a first trial.

Perhaps it is the wish of "A Worker" that the pellicle should be as useless as he says it is! R. KENNETT.

[The prints enclosed by Mr. Kennett are exceedingly fine, and in no way distinguishable from good wet plate work, being singularly delicate and full of detail, and perfectly brilliant.—Ed.]

#### THE LATE EXHIBITION.

SIR,—Will you kindly give this grievance publicity in the PHOTOGRAPHIC NEWS? I received my five photographs, returned from the Exhibition in London, in a most disgraceful state, they having been put into the case loose one upon another without any attempt at packing. The consequence was that two of the glasses were broken to smash, and the frames injured. I wrote to the Secretary on the subject, but he did not reply to my communication. Such carelessness ought not to be allowed; there should be some responsible person to see that proper care is taken in returning works sent to the Exhibition. REUBEN MITCHELL.

*Willow Bank, Sharples, Bolton, November 30th.*

#### IMPROVED TRIPOD STAND.

DEAR SIR,—I cannot remain silent respecting the above. Your correspondent, Sir T. G. A. Parkyns, in your issue of Nov. 13th, says he is disappointed at seeing and hearing of a tripod stand which is so much like his. But I must say that the description is very much like a copy of mine. I do claim improvements, but not the stand itself; neither can Sir T. G. A. Parkyns, for it has been in use for many years, as Mr. Hughes remarked at the South London meeting; but we improved it, and again brought it before our photographic friends, believing it to be a useful and much needed stand.

I can show by my books, and can give the names of parties supplied with the same many months previous to the time that Sir T. Parkyns states; and what I claim as copyright is the drawing only, and I shall take proceedings against anyone copying or making use of the same without my permission.

As to the latter set mentioned, I may say that the one exhibited at the Cambridge Hall, Oxford Street, was a No. 1 stand, and will raise a camera from three to five feet six inches high, and the No. 2 from four feet to seven feet. This, it will be seen, admits of more extension. I contend that the ball and socket joint is far preferable to a block simply turning round in a socket; for instance, by means of a ball and socket, if the object is not just in the square or centre, I can adjust the camera by simply loosening the screw under the ball, and set it as required, and then screw up again; whereas if the block turning in the socket is used, you must stoop and loose the screw in the leg, and in many instances shift two legs and perhaps more, then, in or out, to get the required adjustment. Also the plane is not always required the same for taking panoramic views or moving objects, and if it should be, the ball and socket will answer all requirements.

The bolts in my stands have large heads, and under the fly nut is fitted a large brass washer, so that the wood cannot wear away with constant using.—I am, yours faithfully,  
W. H. OAKLEY.

202, Grange Road, Bermondsey, London, S.E.

### Proceedings of Societies.

#### AMATEUR PHOTOGRAPHIC ASSOCIATION.

A COUNCIL meeting of the above Society was held on the 23rd instant, at 12, York Place, Portman Square, Lord De Ros in the chair. The minutes of the last meeting having been read and confirmed, the following members were elected:—H. B. Southwell, Esq.; H. R. Robertson, Esq.

In conformity with a notice given by Mr. Glaisher at the previous meeting, Lord De Ros was elected Vice-President, and T. Sopwith, Esq., was elected Referee.

The SECRETARY laid before the meeting a revised copy of rules, which were passed by the meeting, and are as follows:—

Rule 1.—A subscription of one guinea per annum shall be paid by each member and subscriber.

Rule 2.—Members shall consist of none but *amateur* photographers.

Rule 3.—Other persons not photographers, wishing to avail themselves of the advantages of the Association, may become "subscribers."

Rule 4.—Each member shall be entitled to select two guineas' worth, and each subscriber one guinea's worth, of photographs every year, free of charge, from the Association prints, subject to such regulations as the referee shall determine.

Rule 5.—Members shall be supplied with all *additional* photographs at half, and subscribers at three-fourths, of the usual prices.

Rule 6.—The Council will at all times hold the Secretary responsible for all negatives entrusted to the Association, but no commercial use being made of the plates, the responsibility is limited to fair wear and tear and inevitable accidents. The Council recommend that all negatives be sent in grooved plate-boxes. Such negatives shall remain during the year for which they are sent, but if special application is made, they will be returned within one month after such application has been received by the Secretary.

Rule 7.—Each member will be expected to forward as many good negatives as he conveniently can, and any member sending less than six during the year may, at the option of the referees, be ranked as a subscriber.

Rule 8.—Copies of every negative in current circulation shall be kept in stock by the Secretary of the Association.

Rule 9.—Prizes to the amount of not less than fifty pounds shall be awarded each year by the Council, to whom is reserved the right to fix the number, arrangement, and relative value of the prizes.

Rule 10.—Any differences which may occur shall be referred to the referees, and their decision shall be final. The prize negative shall become the property of the Association, but in any case the proprietor shall be at liberty to decline to part with his negative, whereupon another shall be selected for the prize.

A. J. MELNISH, Hon. Sec.

### Talk in the Studio.

PHOTOGRAPHIC SOCIETY.—At the meeting of the Photographic Society to be held on Tuesday evening next, Mr. D. L. Mundy will read a paper giving his "Photographic Experiences in New Zealand;" and Mr. W. B. Woodbury will read a paper describing some "Experiments with Coloured Media."

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The Annual Dinner of this Society will take place at the Café Royal, Regent Street, on Thursday, December 17th, when the members will be pleased to see any photographer or friend who may desire to assist at this social reunion. Further particulars may be obtained from the Hon. Sec., Mr. Edwin Cocking, 57, Queen's Road, Peckham.

THE PHOTOGRAPHER'S FRIEND, an American journal, issued hitherto once in two months, in Baltimore, is about to be merged into our excellent contemporary, the *Philadelphia Photographer*.

**EMBEZZLEMENT.**—“An elderly man named John Fahrbaeh,” says the *Daily Telegraph* of the 2nd inst., “was to-day charged at the Dale Street Police Court, before the stipendiary magistrate, with having obtained £265 by false pretences from Julius Hartmann. It was stated for the prosecution that prisoner had represented himself as the manager of the London and Liverpool Photographic Company, and it was alleged that he had obtained the sum named from the prosecutor as a security for a situation as secretary, by false representations respecting the company. The prisoner was committed for trial at the sessions, bail being accepted.”

**THE BRITISH ARCHITECT.**—Referring to our recent paragraph alluding to this journal, the operator engaged in producing the photographs writes as follows:—“In your notice of the *British Architect* on the 20th inst. you express a doubt as to the correctness of the notice on the cover stating it to be the only journal in the world containing permanent ink photographs. I beg to inform you that the notice does not refer to the photolithographs of line drawings contained in that number, but to the issue of photographs in half-tone, printed in printer's ink, and of which the enclosed are specimens; the other journals to which you refer being illustrated in line work only, and those in England being Woodburytypes, and not printed in greasy ink. If you will have the kindness to state these facts you will oblige.” Some good architectural photographs in half-tone accompany the note, which we are glad to see. We should still point out that the sole claim made is scarcely accurate, as some of our continental contemporaries send out frequent examples of photo-colligraphy, giving fine half-tone, produced, of course, in printer's ink; but whether with as much frequency or regularity as the *British Architect* we cannot say.

**SOLAR PHOTOGRAPHY.**—“A physical observatory,” says *Nature*, “is soon to be established in Paris; and a recent vote of the Academy, appointing a commission to report on the subject, will not be lost. It is said that M. Janssen is to be the head of the establishment, in which solar photography will be practised on a large scale. It is also supposed that the observatory is to be ready by the time M. Janssen returns from Yokohama with the instruments.”

## To Correspondents.

**THE YEAR-BOOK OF PHOTOGRAPHY FOR 1875.**—We have again to thank many friends for interesting contributions received during the week; and we may again remind our readers that we shall be glad to receive bits of experience and suggestion from all observant workers, as it is by the gathering together of the knowledge of many that our annual has acquired its position as a favourite with all.

**F. C. S.**—If you have not access to any working optician or ordinary brass finisher, probably any London dealer will get the lacquering done for you. Possibly you may do it yourself if you care to try. Take shellac varnish and add either gamboge or dragon's blood, as you prefer a yellow or an orange tint, and add sufficient to give the proper colour. Clean the brass-work well with soap and water, then make warm and apply the varnish. Finally, let the brass-work remain in a warm place for some hours, to permit the varnish to become thoroughly hardened.

**J. J. T. G.**—Your work is exceedingly creditable for a beginner; the only faults they possess being easily remedied. They consist in slightly under-exposing and slightly over-intensifying, the result being a little hardness; that is, there is great contrast of light and shadow, without sufficient detail and modelling. The standing figure is best, but it is just a little chalky in the face. We are glad to learn that you find the *NEWS* so useful. We shall have pleasure in hearing from you from time to time, and shall always be glad to aid you with confirmation or advice.

**J. L. R.**—The matt silver stains like oyster-shells, and at times like slug-tracks, are due chiefly, in your case, to a repellent film, arising from the somewhat horny character of the collodion. It will improve as it gets older, and will yield a less repellent film. In the meantime, you may try the addition of a few drops of glycerine to each ounce, which will probably effect considerable improvement. Great care and cleanliness will also aid you in avoiding the stains. Keep the inner frames of your dark slide well washed, and let the plate rest on strips of clean blotting-paper.

**CAPTAIN TURTON.**—Thanks. There is a curious conservatism about professional photographers, which makes them indisposed to try other than safe and recognized methods. Regarding a society, why not try to establish one?

**AMATEUR.**—By no process of cleaning will you be able to make a beer cask a suitable vessel for holding distilled water for photographic purposes. If the cask were perfectly new it would be unsuitable, as the water would gradually get contaminated with organic matter from its contact with the wood. You must keep distilled water in an earthenware or glass vessel. 2. We cannot speak with certainty of the relative excellence of the paper you name and freshly sensitized paper, not having made comparative experiments; but we think it probable that the permanent paper will give just as good results. It does not require all the silver washing away before toning. We do not know of any better durable sensitive paper than that you name.

**E. J.**—The smallest packet of the sensitive pellicle requires two ounces of water adding—warm water, of course. 2. The time it will keep after mixing will somewhat depend on the weather—probably a week or two in winter. 3. If you find difficulty in getting it to flow over the glass, you may lead it with a clean glass rod. 4. The plates will keep well after they are prepared; but how long we cannot certainly say. 5. You had better follow the printed instructions in developing.

**AN OLD PHOTOGRAPHER.**—The silver will be recoverable by almost any of the processes used for recovering the silver from hypo baths. In this case a simple plan will be to make the solution acid by adding a few drops of sulphuric or hydrochloric acid, and then place a few strips of clean zinc in the solution. This will throw down the silver in a fine black metallic powder. Wash with dilute sulphuric acid to remove traces of zinc, rinse well, and then recover the silver into nitrate by adding nitric acid.

**F. H. WORSLEY-BENISON.**—An intense black tone is best obtained in ordinary albumenized prints by using the lime toning bath, made by adding three grains of chloride of lime to two grains of chloride of gold in twelve ounces of hot water. It may be used when it is quite cold, and keeps well. The negatives should be vigorous, permitting a deep deposit of silver in the blacks of the print, giving a slight bronzing. Such prints, with such a toning bath, will yield rich black tones. The especial tones to which you refer, however, in Mr. Bruce's pictures at the Exhibition, are only obtained on collodio-chloride paper, which Mr. Bruce uses for all his work. You will find full details of it and of his mode of working it in his paper read before the Photographic Society in the spring, and printed in our pages at the time. A similarly black tone on other paper, without the delicacy of the collodio-chloride surface, would look somewhat heavy.

**A. C.**—We should prefer No. 2, as doing the work as well and much more rapidly. No. 2 will answer your purpose as well, we think, as the third you name, and certainly will answer best for all round work.

**DRY-PLATE NOVICE.**—Albumen may frequently be used with advantage as a substratum for dry plates, especially where the ordinary acid development is used. For the gum-gallic process, Mr. Gerdon used to employ india-rubber. He found that the india-rubber solution for preliminary coating to gum-gallic plates should not exceed one and a-half grains to the ounce of chloroform, and should not fall below three-quarters of a grain to the ounce. As the solvent is exceedingly volatile it will soon get thick from use, and this must be looked to. If the plates are to be used fresh, they may be employed without a substratum at all, merely applying an edging of india-rubber before developing. In this case all the film becomes loose, except at the edges, forming one huge blister, which, after fixing and washing, may be punctured. The film then subsides and leaves no mark. 2. Alkaline development may be used with collodie-albumen plates, but it requires care to prevent stains.

**SENEX.**—The easier mode of using a flat dish for sensitizing negatives, without risk of stains or lines across the plate, is to employ a dish sufficiently large to permit the plate to be laid flat in the dish, face up, before the solution touches it. To manage this, the dish should be raised up at one end, allowing the solution to flow to the other; the plate is then laid down in the empty portion, and the dish being again brought into a level position, the solution flows over the plate in an even wave. A hook of silver wire is used to lower the plate, and to raise it again when sensitized. There are well-baths and cradle-baths made to facilitate this work; but, with a little skill and care, it is not difficult to do it with an ordinary flat dish. We recently saw M. Lambert, in Paris, working plates 24 by 20 in a simple flat dish, without any assistance. He lifted the large wooden dish out of the level with his knee, holding the large plate with both his hands. This being placed in the empty portion of the dish, the knee was lowered and the solution evenly flowed over the large plate without causing a line or stain of any kind.

**J. SIMPSON.**—No. There is no work on Africa as a field for photographic experiments, nor indeed any special work devoted to photography in tropical climates. Occasional letters and articles on the practice of photography in hot countries have appeared in our pages. We regret that we do not know of any skillful landscape or out-door photographer who undertakes to give lessons.

**J. E. and C. J. EVZ.**—Thanks. We shall use the communications in our *YEAR-BOOK*.

Several Correspondents in our next.

## The Photographic News, December 11, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO. PHOTOGRAPHY AND HOUSE AGENTS—HOW TO PRODUCE PHOTO-RELIEF PLATES.

*Photography and House Agents.*—One of the most useful everyday applications of photography is undoubtedly that of employing it in connection with the letting and selling of house property. A photograph helps us to form a far better idea of a house and its neighbourhood than any other means, short of visiting the place, would do. House agents and auctioneers are well known as an enthusiastic class of men, and prone to exaggeration on the slightest excuse; in fact, we all know that there is scarcely anything so interesting and fascinating as reading the auction advertisements of the *Times*. In many cases it seems as if the auctioneers were quite incapable of describing, within the limits of two inches of type, all the charms and comforts of a mansion, with its dining-rooms and billiard-rooms, its conservatory, terraces, &c., which happens, most fortunately, to be in a most secluded spot, and yet in close proximity to half a dozen railway stations. You are at once possessed with an indescribable longing for the possession of such a charming residence, a desire which is sometimes cured very quickly when a photograph of the fascinating *Chaieau d'Espagne* is put before your eyes. It is all very well for the agent to explain that the picture was taken at a most unfavourable season of the year, and that it does not show the improvements that have since been made to the property. There is no mistaking the stucco front, the mean little portico that has been made so much of, the roughly-turfed banks and struggling shrubs that constitute the terrace and plantation. Or if it is some roomy semi-detached villa in a pleasant suburb that is to be disposed of, the photograph shown will at once demonstrate whether it is a residence that may be suitable, or not. You see at once if it is really a substantial edifice in a good cheerful thoroughfare, or whether the eligible house and grounds is one of a cheap lot of rubbishing tenements run up by a bankrupt builder in some forlorn district. And this subject of photographing houses and estates for purpose of advertisement calls to mind the unsatisfactory way in which some of the models are treated. While it is difficult enough to make a dwelling appear more favourable than it is, it is very easy to make it look more uninviting than it is under ordinary circumstances, and, as a rule, photographers who are entrusted with the work do not do as much as they might towards rendering things pleasant and comfortable. If, for instance, there is a foreground of road, footway, or waste land of a rugged nature, it is obviously bad policy to use a wide-angle lens, and thus exaggerate a defect which is already bad enough; or if the villa or tenement is perhaps a little less lofty than it might be, then care should be taken not to make this weakness more obvious than necessary. We have seen pictures of terraces and streets of a most woebegone character, which might have had a much more cheerful aspect imparted to them with the use of a different lens and the addition of a little life in the form of a cart or two, and half a dozen passers-by. A little care taken by the photographers in these matters would aid the agent very materially in getting the property off his hands.

*How to Produce Photo-relief Plates.*—M. Fink, of Vienna, has suggested a plan of producing photo-engraved plates, of the same kind as the Woodburytype blocks, different to that usually adopted. He dissolves half an ounce of bichromate of potassium in seven and a half ounces of water, and this solution is then warmed, and one ounce of gelatine gradually added. When nearly boiling the liquid is filtered through muslin, and the filtered liquid spread over plates so as to form a layer one and a-half lines in thickness; this is, of course, done in the dark room. The dry sensitive film is then printed under a transparent

positive, about ten to thirty seconds sufficing in a diffused light; the impression is taken back into the dark room, and transferred from the printing frame into luke-warm water, where it remains till the image is seen strongly in relief, when it is dried by blotting on filter-paper, and covered with a little glycerine. After this the gelatine mould is covered with a layer of plaster of Paris, and when this matrix is removed, type metal of a fusible nature may be poured in, and a printing block thus secured.

### PHOTOMETRIC VALUE OF THE DIFFERENT LIGHTS USED FOR LANTERN PURPOSES.

BY J. M. TURNBULL.\*

HAVING given a good deal of attention, both last winter and what spare time I have had in the last two months, to the perfecting of the lamp which I intend to introduce to your notice this evening, I was naturally led to also examine and compare with one another the different lights used for lantern illumination, the results of which I wish to embody in the following remarks.

I have used all the different lights, more or less, in my varied lantern experience; but what I have of late been directing my attention to, and what I wish more particularly to speak of just now is, their photometric or lighting value as compared with a standard candle.

I am not at present on the subject of photography, but I cannot help remarking here on the mutual benefits which photography has conferred on the lantern, and the lantern on photography. Previous to the days of photography, the lantern was little better than a toy; then good pictures for it were both scarce and expensive, and in the hands of a few; while at the present time, thanks to photography, infinitely better and more truthful pictures can be got for it, at prices so moderate as to put them in the hands of many who would never otherwise have had them. Photography is also gradually raising the lantern to be a necessary instrument for educational purposes, and will, in the course of a few years, be looked upon as an indispensable instrument for that purpose. It now only requires a good and easily worked light to make it more adapted than ever it has been by those who do not care to take the trouble with lime light. This, as you will see, I have tried to add my mite to. On the other hand, the lantern has done photography good by raising up a distinct and important branch of it, namely, the production of lantern slides. With these remarks I will enter on the subject which more nearly concerns us.

The method of comparing two lights looks, when explained, a very simple matter indeed. Let us take first of all the two lights to be compared, place them at the distance of a few feet from each other; but to measure them we require a photometer of some sort. Let us take one of the simplest forms of it; viz., that of Bunsen's, which consists merely of a piece of bibulous paper of a circular form, and mounted on a wire frame. A piece of filter paper answers the purpose very well. A single drop of oil of any sort is put on the centre of the paper. If this spot is now looked at by transmitted light, it appears transparent, but if looked at by reflected light, it will be darker than the paper. The paper screen is now placed between the two lights at such a distance from each that the spot appears equally illuminated on both sides; the distance from the screen to each light is then measured. Suppose we find that the distance from the screen to one light is two feet, we then square this figure, which gives us four; we then find the distance from the screen to the other light to be, say, four feet; we also square this figure, which gives us sixteen; we then divide the one by the other, which gives four as the result—that is, one light is four times the intensity of the other. This is in accordance with the well-known law that light diminishes according to the square of the distance.

This photometer, though very simple, cannot be relied on for any degree of accuracy, especially if the lights to be

\* Read before the Edinburgh Photographic Society.

compared be of a slightly different colour. This remark applies with greater force to another photometer which is very commonly used, viz., Rumford's, which consists of a piece of wood, either round or flat. The lights are so placed that the two shadows of the wood are thrown on a screen, either white or transparent, and the lights moved till the shadows are supposed to be equal; but if the lights to be compared be anything of a different colour, this method is of very little use.

There are, however, various other forms of photometers which give more accurate results. Amongst these may be classed those of Wheatstone and Ritchie. The photometer which I used in my own experiments was that of Ritchie; it gives considerable accuracy, but is not capable of giving very fine results.

There are two other forms of photometers which are said to give very great accuracy, viz., those of Zollner and Babinet. In both of these polarised light is used. That of Zollner is described and figured in *Poggendorf's Annalen*, vol. c. This form of photometer was used by Dr. Robinson, of Armagh, in estimating the light transmitted by different telescopic object glasses. He says that it can be made to give results thirty-five times more accurate than by the method of moving the lights (see his paper, *Trans. Roy. Soc.*, vol. clix., p. 157). The other form—viz., Babinet's—is also an application of the principle of polarized light, but is more complicated than that of Zollner. It was described by the inventor in a paper read before the British Association in 1864, Liverpool meeting. I have not had an opportunity of seeing either of these two photometers, but as I am not altogether satisfied with the accuracy of the results obtained with Ritchie's form, I intend returning to the subject again.

It is usual, in photometric experiments, to have a standard or unit of light with which to compare the light to be tried. The standard usually used is a sperm-candle, burning at the rate of 120 grains in the hour. This is termed the Standard or Parliamentary candle. Should the candle burn more or less than 120 grains, a correction will require to be made for the same; but with the candles I used, I found that no correction was necessary. My method of comparing the lights was to place the light to be tried in the lantern, and to place the candle on one side of the photometer and the lantern on the other, and having found the proper place when the lights were equal, the lens was screwed out of its place, and the condenser also removed, and the distance measured from the light to the photometer, and also from the candle to the photometer, and the distances squared.

The lens used in these experiments was a card lens of  $2\frac{1}{10}$  inch, 8 aperture, and  $4\frac{3}{4}$  inch focus. I have found that this form of lens is the best I have ever tried for lantern purposes; it can be used with nearly the full aperture; it both gives a great deal more light, and also a much sharper picture, than the lenses in common use for the lantern.

I shall now give a list of the different lights I tried, with their value in standard candles, and then make a few remarks on each of them.

Argand gas lamp ...	=	30	standard candles
Fountain oil lamp, with $1\frac{1}{2}$ circular wick ...	=	39	" "
Hink's duplex, $1\frac{1}{4}$ wicks, not tried in lantern ...	=	13	" "
Sciopticon ...	=	$42\frac{1}{4}$	" "
My own lamp ...	=	58	" "
Lime light ...	...		

The light from the Argand gas lamp varies very much, both owing to the burner used, and also to the illuminating power of the gas. In many towns the light will not nearly be so much as I make it, owing to the low illuminating power of the gas; it is also sometimes deficient from there being little pressure of gas. If that is the case, the wire should be taken out of the india-rubber tubing, which will help to increase

the light. The principal recommendation that this burner has is, that where gas can be had, it gives you very little trouble.

The Fountain or Solar Lamp. If care be taken to keep this lamp clean, and to trim the wick properly, it gives a very good light when the disc is not too large. Sperm oil is the proper thing to burn in it, but good colza or olive oil is nearly as good. The oil does not burn well at first, being cold and thick; it should therefore be made pretty hot previous to being placed in the lamp, or the lamp, with the oil in it, should be set at the side of a fire for some time. To see when the wick is properly trimmed, it should be lighted, and then turned down very low, when a nice even ring of light should appear.

We now come to the paraffine oil lamps. I may here remark that paraffine oil is more suited for the lantern than either gas or sperm oil; it has a sharper and more intense light than either.

Hink's Duplex, with double wicks. I had not an opportunity of trying this lamp in the lantern, but it gives a first-rate light for house illumination, judging from the argand gas lamp, which gave, when burned out of the lantern, a light equal to thirteen candles. I should say the Hink's lamp would be equivalent to about thirty candles when burned in the lantern. Any party having a lamp of this kind in their house can easily adapt it for the lantern by having a tin reservoir made of a suitable size to fit the lantern, and having an extra flange on the top of it, in which to screw the burner of their lamp. The edges of the wicks should be turned to the condenser.

The Sciopticon. This very ingenious lantern and lamp combined gives a better light than any of the lamps I have yet noticed. The fountain lamp, however, comes pretty close on it as far as light goes, but the Sciopticon is much more easily worked. It is a great improvement on the old form of lantern. It has, however, one defect which tells a good deal against it: as the edges of the lights are opposite the condenser, there is a space between them, which is reproduced partly on the screen; it thus does not give an evenly illuminated disc, which helps to spoil the effect of the picture shown, more especially if it be a delicate or fine one.

I now come to my own form of lamp. This is a great improvement, as far as regards brilliancy of light, on any other form of oil lamp that has been used for the lantern. It is equal, when burning under the same conditions as the other lamps, to fifty-eight standard candles. It gives a clear white brilliant light. In constructing this lamp, I have aimed more at getting a small quantity of extremely white light, than a larger quantity of yellowish light, which is not nearly so good. The smaller and more brilliant the light is, the better is it suited for the lantern. We have only to look at the lime light to illustrate this. As this form of lamp is meant to burn with edges of the lights to the condenser, it has the defect I have already spoken of in the Sciopticon, though in a less degree; but this is entirely remedied by turning the lamp very slightly to either side, so that the wicks are not in a straight line to the condenser; it will then give a beautiful, clear, and evenly illuminated disc on the screen. It will burn well in any ordinary lantern, and gives very little trouble, as it can be lifted in a few seconds. The cost of burning it is also very cheap, being something like one-halfpenny per hour. The light being very actinic, it is also first-rate for enlarging negatives.

The lime light. I give the value of the lime light in standard candles as used at our Society's Popular Meetings, but I do not here intend to say much about it. We all know its surpassing excellence for the lantern; but it requires some experience to work it well and safely. For large exhibitions it cannot be dispensed with; but for private use it is not every one that cares to be at the trouble and expense connected with it.

## "THE SPIRIT OF THE JOURNALS."

BY W. T. BASIFORD.\*

THE month of October has seen much activity in all photographic circles. The American Conference met at Chicago, held a very successful exhibition, and before it closed liquidated a debt of \$3,500. Many interesting papers were read and discussed, many questions instructively answered, and much complacent talk was indulged in. The South London Technical Meeting has been held, a number of useful things were exhibited, and much friendly discussion took place. The London Photographic Exhibition was opened, with contributions from some of the leading workers, both home and foreign. Of course, much of the matter in the English journals relates to this large collection of pictures, and though the editors have kindly done their best to make things look as bright as possible, there is a suspicion of disappointment at the bottom of all they say. From personal inspection, I think that disappointment well founded; at any rate, with very few exceptions, the work exhibited was not of a character to excite enthusiasm. There seems still a jealous suspicion that matters are not conducted with fairness, and so long as this obtains, a hearty response from all our best workers to the invitation of the committee will be looked for in vain.

This month has given birth to two photographic societies, one in Yorkshire and the other in Belgium. The latter is quite a national affair, with its monthly journal illustrated by photography, and sections located in various parts of the country, as Brussels, Ghent, and Liege, &c. Reading its constitution makes one long for something similar in Great Britain. Surely it is time for such a movement to be set on foot. Nearly all the old societies have given in their reports, which, on the whole, are satisfactory, and, with each, work for the winter session has begun in earnest.

We have a valuable contribution to science in a series of papers, by Dr. Miller, exhibiting close experimental research, on the "Actinic limpidity of various gases, liquids, and solids; together with the photographic effects of various spectra obtained by means of the electric spark." Messrs. Sutton and Bolton are engaged in courteous discussion on the theory of the latent image upon an organized bromide of silver film. When two such able thinkers, experimenters, and writers attack a problem, the result cannot but be watched with the deepest interest and edification. In my estimation, Mr. Sutton is the light of photographic literature, and our fraternity throughout the world is to be congratulated that he still continues his weekly contributions.

The Editor of the *British Journal* opens the month by teaching us how to squint philosophically; this he does that we may be enabled to (a) see stereoscopically, without investing three shillings and sixpence in a stereoscope, (b) detect wrongly-mounted stereographs, and (c) know the actual appearance of a stereograph from the image on the focussing-screen of the stereo-camera: advantages by no means to be despised.

Interesting and instructive papers appear in favour of fuming sensitized paper, with the rationale for so doing; and the ammonia-nitrate bath with alcohol is recommended as a substitute for those who fear the trouble or imaginary danger of fuming. I would, however, warn those who may be tempted to try the methods suggested that, in its present state, it does not answer as well as might be wished.

Mr. Foxlee contributes a series of exhaustive articles on saving and reducing residues. They are evidently the outcome of practical experience, and the advice given is, of my own knowledge, thoroughly to be relied on.

Our American cousins are always specially prolific in formulae, and the past month furnishes quite a large selection. It is a curious fact, that when a photograph possessing special merit is exhibited, we find quite a number of people anxious to know the formulae by which it was pro-

duced, as though the beautiful results of much anxious study and unwearying exertion were the mere product of so many grains of gun-cotton, or so much acid, or, perhaps, a little morphia or zinc in the developer! With such process-mongers and mechanical dabblers photography would not rise to the work of a baker who weighs his currants, sugar, and butter; for while the latter may always produce uniformly good edibles, the former will often find his best efforts only give a wretchedly disheartening daub. Photography in its highest phase is the wedding of art with science, and an artist-photographer is no more governed by exact formulæ than he is by the ignorant nonsense with which some art scribblers fill up their paragraphs. There is often as much sense in asking a photographer for a formula, as in asking an artist how many bristles were in the brush by which he produced the sparkle in the eye, or dimple in the cheek, of one of his best portraits. And it is very encouraging to find that in the majority of the formulæ elicited from the exhibitors at Chicago, "great care," "much time," "long study," and such like expressions are principal factors; as with all works of art the chief ingredient of a very old formula is necessary, namely, "brains."

From the Continent we have Professor H. Vogel dealing with the same subject, while giving sensible advice to beginners. He recommends a sound theoretical knowledge, supplemented by a thorough practical experience under a really clever teacher, as a necessary foundation for all who are anxious to excel in our beautiful art-science; and sums up by stating that it is only long practice and study that make the skilful photographer.

At Chicago, Mr. St. Clair exhibited great distress at the danger to which photographers exposed themselves by adding glycerine to the negative bath, asserting that in such cases nitro-glycerine was immediately formed. Some gentlemen even testified to the losses they had sustained from this cause. Surely there is some mistake here! I always understood this dangerous compound was never formed except in the presence of sulphuric acid. I have used glycerine in my negative baths and collodion, yet, thus far, have received no injury from so doing; and since reading this I have boiled down an old bath to fusing without danger, yet this bath had a liberal dose of glycerine in it.

M. Cornu has introduced an ingenious plan for correcting astronomical objectives for the chemical rays; it consists simply in separating the flint and crown lenses of the object-glass about a half per cent. of its focal length. This operation will shorten the focus by about one-twentieth, and the aperture must be reduced by means of a diaphragm, so as to retain the same angular aperture. The same gentleman intends employing the Daguerreotype process for observing the coming transit of Venus.

A really valuable method for obtaining dense negatives is contributed by the esteemed French correspondent of the NEWS, M. Ernest Lacan. A very thin negative is obtained by ordinary iron development, and fixed in the usual way; it is then placed in an alcoholic solution of bichloride of mercury, after which a solution of iodide of cadmium is poured over the plate until all the bichloride is converted into the proto-chloride. There must be a careful washing between each operation. I have pleasure in submitting a copy of an engraving done by this process. The engraving is from a periodical, the thin paper of which was much discoloured, and the whole of the back was covered with letterpress, which showed through on the face of the engraving; yet it will be seen that the reproduction, from the finest lines to the broadest lights, is perfect.

Those who wish to experiment with the beautiful collodio-chloride process have presented to them a method of preparing two stable solutions, which, on mixing in equal proportions, make excellent collodio-chloride ready for immediate use; and in the same column of the NEWS may be found some suggestions on the management of

\* Read before the Edinburgh Photographic Society.

development. Time and space will not allow of its reproduction, but those who have not read it should turn to page 470. Those who have no faith in what is recommended should try it, and if they see nothing in it, try it again. I always employ a somewhat similar method, and cannot understand how any photographer can afford to do otherwise.

M. Edmund Becquerel contributes a most interesting paper on the action of rays of different refrangibility upon the iodide and bromide of silver; and in concluding, supports Dr. Vogel's observations on the value of various colouring matters (notably chlorophyle and coralline) being mixed with the collodion in order to render it impressionable by the red, yellow, and green rays, propounding several theories to account for the facts that repeated experiments have established.

In the *Revista Fotografica*, Signor L. Borlinetto publishes details of his new process for obtaining photo-lithographic transfers, by the addition of alum and nitrate of silver in different stages of preparing the ordinary gelatine film. He claims that the proofs are superior to those obtained by any other method yet published.

In connection with this subject, may I reiterate the appeal of a correspondent, "Will somebody invent a small and cheap lithographic press?" I think that by this time all difficulties in the way of reproductions in fatty inks would have been overcome, if the many amateur and professional photographers who are interested in the matter had placed within their reach a lithographic press for practical experiments.

A negative, from many causes, may be so damaged or imperfect as to be entirely unfit for the illustration of a book of travel, &c., yet a very imperfect print may be much superior to a hand sketch; and it is suggested by the Editor of the *British Journal* that such imperfect negatives may be utilized in the following manner:—Obtain prints of a blue colour by one of the ferrotype processes, then trace or etch over this in black ink, omitting all defects; a correct drawing is thus speedily obtained. Copy this by photo-lithography in the usual way.

Are we ever to have photography in natural colours? There are those who say unreservedly that it is an utter impossibility; others, by the superposition of very thin films of pigmented gelatine, representing the primary colours—each film produced from a special negative—hope to get a combination that in form and colour shall exactly represent the original model. By a somewhat similar principle others hope to get chromographs by the Albertype and allied processes. The last phase is that in which, by the direct action of light alone, the primary colours are themselves formed in separate films, which it is hoped, by superposition, will produce a correct chromo-photograph. All these modes are ingenious, and the author of each deserves all honour for his unremitting exertions, fighting almost single-handed against difficulties that met him at every step; not the least discouraging would be the cold indifference exhibited by those who would reap the greatest benefit should his desires be realized. I do not now hear of any hope that a photographic positive in all the richest colours of the original can be directly produced in the camera, yet I have seen one such,—and never shall I forget the sight, or the excitement it produced.

An excellent article appears in the *Philadelphia Photographer* by Mr. Chute, on the proportion of light and shade in the photograph. It is especially worthy of thought and application at this time, and at this part of the country, where the style known among the vulgar as "Rembrandt photographs" is much in vogue. There is, however, little doubt that when the reaction sets in, as it has long ago done elsewhere, photographers will be great gainers by the knowledge they have acquired in seeking their sometimes startling abominations. Sir Joshua Reynolds found, after critically examining the works of those artists who best understood the management of light and shade, and whose works were the most universally pleasing, that their

general practice was to allow not above a quarter of the picture for the light, including in this portion both the principal and secondary lights; another quarter to be as dark as possible; and the remaining half kept in mezzotint or half shadow.

Our indefatigable corresponding secretary, Dr. Nicol, gives us the results of a series of experiments instituted in order to find out the value of supplementary exposure, and among his racy "notes" he makes some well-timed remarks about Mr. D. Winstanley, and what he sells as a secret.

Mr. Marchand has invented an apparatus for measuring the intensity of chemical rays; it is founded on the disengagement of carbonic acid from oxalate of iron under the influence of light. He has had it in action for the past five years. From the behaviour of the apparatus the inventor concludes that the chemical intensity of a June day is nearly twelve times that of an average day in December.

Dry plate workers have a happy future before them if all that is said about Mr. Phipps' bromide emulsion process may be relied on. Full details, from the manufacture of the emulsion to the development, may be found in his paper read before the Liverpool Photographic Association. It is similar to Mr. W. B. Bolton's process, and seems extremely simple. The plate requires no washing after it is coated, neither is a preservative applied. A large quantity of the emulsion may be made at one time, as it keeps indefinitely.

The Editor of the *Philadelphia Photographer*, in his extremely amusing "views abroad and across," which I am sorry to find are so soon drawing to a close, gives Liebert's process for enlarging negatives, which he is convinced is the same as a certain English process that has been much advertised during the past year. It is a modification of the collodio-albumen process applied to positives for transparency. Prepare the following iodizing solution:—

Iodide of ammonium	... 4 grammes	(61½ grains)
Bromide of ammonium	... 1½ "	(23 " )
Distilled water	... 75 "	(2½ oz. troy)

Add this solution to the whites of four eggs, about 100 grammes (3½ oz. troy). Beat to a froth, and allow to stand twenty-four hours, filter, albuminize the selected glass plates, then collodionize with any good iodized collodion, and, when quite set, wash under a tap; finish by washing in distilled water. Now cover with five or six coatings of the above iodizing solution, dry, and store away for future use. When a transparency is required, dip this plate, previously dried over a lamp if necessary, into the following aceto-nitrate bath:—

Nitrate of silver	... 80 grammes	(2½ oz. troy)
Crystallizable acetic acid	... 50 c.c.	(1¾ fluid oz.)
Distilled water	... 1 litre	(1¼ quart)

After an immersion of one or two minutes, wash in distilled water, and dry in the dark with care. Now place under a negative in a pressure-frame, and expose to diffused light from five to fifteen seconds. To develop, place in a dish of distilled water to soften the albumen, then proceed to develop with the following:—

Distilled water	... 1 litre	(1¼ quart)
Pyrogallic acid	... 7 grammes	(108 grains)
Acetic acid	... 30 c.c.	(1 fluid oz.)

The image will present a weak appearance, but may be intensified by adding a few drops of the following:—

Distilled water	... 1 litre	(1¼ quart)
Nitrate of silver	... 20 grammes	(380½ grs.)
Citric acid	... 5 "	(77 grs.)

Continue the development until the image has arrived at the requisite degree of intensity. Fix in hypo or weak cyanide.

#### ON AN UNSUSPECTED CAUSE OF SPOTS ON C.D.V. AND CABINET PHOTOGRAPHS.

BY W. T. BASHFORD.\*

THESE has not been a month during the past two years in which the photographic journals have not been engaged in

\* Read before the Edinburgh Photographic Society.

discussing the origin of numberless pepper-like specks that make their appearance on photographs. Several things have been held guilty for their appearance. One suggests imperfect fixation; another, careless washing; a third thinks they are caused by minute particles of iron, either in the metallic state or in the form of a salt, which find their way to the prints in the shape of dust; a fourth imagines the disease original with poisonous spores, and at once writes learnedly on the matter, arguing that measly photographs and measly children owe their disease to the same origin; while a lady is certain they are caused by tobacco ashes dropped from the cigars of her male friends. It is, however, generally acknowledged that one very fertile source, if not the chief—or, perhaps, only—cause, is the bronze powder used in printing photographic mounts.

I have for several years entertained the latter opinion, and, consequently, I determined that no bronze printing should enter my establishment. With this object I directed that my cards and other mounts should be printed in anything but gold-bronze, and in giving these orders I always stated my reason for so doing. Having done this, I felt at ease in regard to that trouble. Judge, then, of my disgust when the disease appeared upon my prints after all my care. These specks only appeared upon my cabinets, and then only when mounts from a new batch were employed. About this time some one suggested hypo in the mounts, but I judged the fading would be more uniform, or in larger patches rather than in well-defined dots, if hypo were the cause; and on examining the mounts with a magnifying glass, I found the cards were covered with my old enemy bronze-powder, the very thing I directed should not be used. This unexpected discovery leads me to warn my brethren not to be too certain that their own cards are free from this defect. In all probability my cards were printed near other cards that were being finished in bronze, and the fine dust will find its way in all directions if there be the slightest motion in the air.

I purposed bringing an unopened package of these mounts for your inspection, but our Secretary having called on me a few days ago, a package was opened in his presence. He drew his finger across several, and found the end of his finger presented quite a glittering appearance from the adherence of the dreaded particles. I have brought a few of the cards, which I lay on the table for the inspection of those interested. To be warned is to be forearmed, and my past experience will have been cheaply purchased if, by directing attention to this unexpected cause of fading, I remove one of the many difficulties which others, as well as myself, have to fight against while pursuing the fascinations of our often abused but much-loved art-science.

REPRODUCTION BY PHOTOGRAPHY OF CRYSTALLINE FORMATIONS AS THEY ARE SEEN UNDER THE MICROSCOPE.

BY M. I. GIRARD.\*

I HAVE the honour to present the Academy of Sciences with a series of photographs of different crystalline formations. In the first place, I experimented with ammoniacal salt, employing a magnifier of a dozen diameters, and afterwards proceeded to secure reproductions of the crystals of bichromate of potash.

There is a great advantage in operating by transmitted light if it is possible, because a greater intensity of light is thus secured. I employed an apparatus consisting of a metal frame-work fixed to a table carrying the camera. This horizontal frame-work was composed of different parts mounted upon a screw shaft, so that they could be moved to and fro from one another, and also nearer and further from the camera, at the will of the operator. The component parts were: 1, the lens, of one centimetre diameter, combined so as to give an enlargement varying from eight

to twelve diameters; 2, a pair of pinchers for carrying the slip of glass upon which the salt has been crystallized; 3, a screen of blue cobalt glass, to give a monochrome light, favourable for photographing purposes; and, 4, a plane mirror, moveable like all the rest of the apparatus, to reflect the solar light in the optical axis of the system.

The period of exposure given varied from an instantaneous one to two or three minutes, according to the transparency of the crystals. When a certain amount of relief is required to make the protuberances more evident, use is made of oblique illumination, by depressing the mirror slightly upon its axis. Although the brilliant effects of polarisation are apparently without any effect upon the photographic film, they permit, under certain circumstances, of detaching the crystals from a black ground, and this allows of details of a delicate nature being produced, which it would be impossible to obtain by the aid of direct light alone. The polarising apparatus is composed of two pieces, the polariser and the analyser; the first of these is placed before the lens, the second between the camera and the lens.

To prepare the crystals for photographing, a solution of the salt is put upon a slip of glass, and allowed to dry upon a perfectly level stand, so that the crystals when the salt is desiccated shall be of the same thickness throughout. It is well to prepare solutions of different degrees of concentration, so as to have a choice in photographing the objects, for some specimens will be found to possess a more definite character than others.

AN ENAMELLING PROCESS.

BY I. B. WEBSTER.\*

THE glass upon which the enamelling is to be done must be scrupulously clean—plate glass, free from scratches, is the best. After being thoroughly cleaned, some powdered talc or French boot powder must be sprinkled on the plate, and with a tuft of cotton rubbed in a circular motion lightly until no traces of the powder are perceived. This gives it a surface which causes the collodion to be easily removed from the plate without sticking. Flow the plate with a collodion made of—

Ether ... ..	4½ ounces
Alcohol ... ..	3¼ "
Gun-cotton ... ..	30 grains
Castor oil... ..	24 drops.

Let it dry, and now immerse the prints in a solution of gelatine made as follows:—

Cox's gelatine ... ..	1 ounce
Water ... ..	8 ounces
Glycerine ... ..	50 drops.

Put the gelatine and glycerine in the water and let it stand all night, when it will be ready for use, after filtering, which may be done by warming sufficiently to render it limpid. After immersing five minutes, take out the prints and place them face downward on the collodionized plate, then roll with a gum roller lightly, to press out surplus gelatine and air-bubbles. After the prints have set for an hour they must be mounted, using gelatine for the purpose, putting it on the back of the print with a brush, and placing the mount on the print, and keeping it in place by means of a glass on the back, with a weight sufficient to flatten. It may remain thus some ten or fifteen minutes, after which the glass can be removed and the whole allowed to dry, which must be thorough, but without the use of heat. Frequently the prints will come off themselves when dry; if not, by running a knife blade around the edges they will easily leave the glass. This formula can only be used successfully on cards and imperials by printing the picture on paper a little larger than the mount; and, by masking the picture, print a border to it representing the black mount, the design for which a patent has been applied for.

## THE TRANSIT OF VENUS.

ON Wednesday morning photography took the chief part in securing one of the most important scientific records to which it has ever been applied since its birth. The transit of Venus, an event the preparations for which have been in progress for some years, and for securing a successful record of which observing parties have been sent to all parts of the globe by different governments, has been successfully observed by the majority of the expeditions from which telegrams have been received. With the nature and importance of these observations the majority of our readers are doubtless already more or less familiar, and we need not dwell in detail upon the matter here. Upon accurate and detailed records of the various phases of the phenomenon depend accurate knowledge of the exact distance of the sun from the earth, at present a matter not definitely ascertained. Upon an accurate knowledge of the sun's distance depends an accurate estimate of its size, and also of the distance and dimensions of the whole solar system. A daily contemporary admirably summarizes the general human interest which belongs to the subject. He says:—"When we consider the wonders which have been revealed by modern researches into the structure of the sun, when we see his noble orb strewn at one time with enormous spots, and at another absolutely without spot or blemish, when we consider how all around his globe are flames of glowing hydrogen, leaping up in places to a height many times exceeding the diameter of this earth on which we live, we recognize the importance of determining the real scale on which these tremendous processes are taking place. It is because we already know the sun to be so far away, and therefore so large, that we find the phenomena of solar physics so impressive, for we know that the very least sign of change detected in the sun's orb from our distant standpoint implies processes so stupendous that the whole earth could not exist even where they were in progress, but would in a few moments be reconverted into the vaporous condition from which she passed millions of ages ago. Regarding the sun as the great storehouse whence the supplies of light and heat necessary for the well-being of our earth are lavishly distributed, we find it a matter of even greater interest to determine on what scale the mighty centre of our system has been framed." Any approach to accuracy in final results can only be obtained by securing the mean of many observations. Minute error in instruments, observations, or records, may most seriously vitiate results when such error becomes a fact in extended calculations. The observations upon which former calculations have been made were comparatively limited, and the means much less perfect than now exist. This is the first occasion upon which

photography has had opportunity of taking part in such an important undertaking, and upon its aid the highest hopes are fixed. We have given details from time to time of the precision and care which have been exercised in the various photographic preparations to avoid possible chance of failure, and the telegraphic summaries which arrived on Wednesday, and appeared in our daily contemporaries yesterday morning, gave ground for belief in complete photographic success. We append some condensed extracts from the telegrams.

The *Daily News* special correspondent telegraphs from Cairo:—"The Egyptian expedition for the observation of the transit of Venus has met with complete success. At the Mokattam Heights and at Suez the egress was observed in all its phases. At Thebes, in addition to these observations, a series of fifty photographs were taken with the Janssen's slide by Captain Abney, including the critical instant of contact."

The Astronomer Royal has received a similar telegram, stating that the results were perfectly successful. We may incidentally remark that this is especially interesting to dry plate workers, Captain Abney having, as our readers know, employed collodio-albumen plates and Col. Wortley's strong alkaline developers. From Roorkee, India, the Astronomer Royal receives similar intimations of success, one hundred photographs having been obtained by Col. Tennant's party. At Calcutta, also, the observations were excellent, and also at Kurrachee. At Shanghai and Madras cloudy weather frustrated the aims of the observing parties. At Nagasaki, Japan, notwithstanding some clouds, successful observations were made, sixty good photographs being secured. At Siberia, also, clouds prevailed, but the photographic operations were successful, and thirteen good plates were secured. Some other results from Asiatic stations remain to be recorded, as well as all the results obtained at stations in the South: tidings not having yet arrived from Australia, New Zealand, the Sandwich Islands, and other points of observation in the Southern Seas.

## FRENCH CORRESPONDENCE.

THE last meeting of the French Photographic Society was scarcely so interesting as the previous one; nevertheless, there was a useful application of the Reflectoscope shown, which is, as I have previously mentioned, an enlarging instrument for opaque bodies, invented by M. Van Tenac. With the assistance of the inventor, M. Davane availed himself of its use to project and enlarge upon a screen some positive prints that had become spotted, and which have recently given rise to discussions on every side. In this way the spots may be studied with ease, and their physical constitution—or, in other words, their characteristic nature—made clearly manifest, so that their chemical cause may be more accurately determined. In this demonstration one was able to judge better of the useful nature of M. Van Tenac's new instrument, and of the importance it will be in scientific demonstrations. The magnesium light, or Solomon lamp, was made use of the other night, but M. Van Tenac profited by the occasion to show the power of illumination produced by a current of oxygen gas passing over the flame of an ordinary oil lamp. The light thus obtained is so white that the gas jets in the hall appeared quite yellow by comparison. Nothing is so simple as the practical application of the system, the employment of which is especially favourable to the reflectoscope to obtain enlargements from clichés. A few seconds only are necessary to produce an excellent negative.

M. Rousselon exhibited to the members of the Society a large series of magnificent prints reproduced from paintings at the New Paris Opera House, by the eminent artist Paul Baudry. But what was the most admired of his exhibits was a new collection of engraved plates of reproductions of paintings, which M. Rousselon exhibited at the same time.

On his side, M. Thiel, senior, showed a fine collection of prints in greasy ink by a process of his own, which is now in full working order. The warmest partisans of the old silver printing process were forced to admit that these reproductions, so varied as regards their subject and dimensions, were in no way behind impressions produced by the aid of chloride of silver. It is indisputable that the method of printing in greasy ink is about to be very widely taken up by photographers, and for this reason particular interest was manifested in a new phototype press, of which I have already spoken as the invention of M. Poirier, on whose behalf it was exhibited by M. Monck. The latter, who has employed the apparatus for some time, showed its capabilities before the eyes of the members.

Much has been said lately regarding the carbon process of M. Lambert, the inventor of Lamberttype. This process is, it is said, so simple, so sure, and so perfect that it constitutes a true revolution in the art of printing in permanent pigments. Before even anything has been published on the subject, a large number of portrait photographers have acquired the right to practise the art—among others MM. Lewitske, Reutlinger, Franck de Villechole, Liébert, Truchelat, Lumière of Lyons, &c. M. Hutinet has purchased, it is said, the patent for England, and the process will be a happy perfection of Lamberttype. This is all I know of the matter at present, but I will not delay making the readers of this journal acquainted with the facts.

MM. Delachanal et Mermet have presented to the Academy of Sciences, through the medium of M. Dumas, the Permanent Secretary, a very exhaustive memoir respecting the lamp of bisulphide of carbon and buoxide of nitrogen, of which I spoke in my last letter. When binoxide of nitrogen is inflamed in a flask containing sulphide of carbon vapour, there is produced a powerful illumination, but the fugitive flame thus obtained may detonate instantly on the mixture of chlorine and hydrogen. The violet-blue tint of the light indicates its high photogenic qualities, and experience confirms the same.

The lamp which allows of the production of a continuous flame of this kind is composed simply of a flask with two openings, of five hundred cubic centimetres capacity. This flask is filled either with fragments of sponge, coal, or, better still, dried pumice-stone, impregnated with bisulphide of carbon. In the central aperture passes a tube, which reaches to within half a centimetre of the bottom of the flask; while to the other opening is fixed a tube of considerable diameter, about twenty centimetres long. This is of glass or metal, and contains iron filings well rammed down. This latter constitutes the safeguard, and prevents the return of the flame towards the reservoir, and is for the purpose of preventing an explosion. Some binoxide of nitrogen is passed into the flask, and the mixture of the two gases is conducted by an india-rubber tube to a sort of Bunsen burner which has been deprived of its supply of air, and of the little conical adjustment which regulates the current of gas; this jet is, in the same manner, filled with iron filings.

The binoxide of nitrogen is produced cold in a large apparatus of M. H. St. Claire Deville; not by aid of the decomposition of nitric acid by copper, which is an expensive method of generation, but by making use of the action of iron upon a mixture of nitric and sulphuric acids in proper proportions.

One of the flasks contains a layer of porcelain fragments, upon which are put some bits of wrought iron; the other is filled with a mixture of acids. The communication is established by means of a wide india-rubber tube attached to the lower openings; finally, a stopcock, passing into the cork of the vessel containing the iron, allows one to regulate the current of gas. With an apparatus of suitable dimensions, a flame twenty-five centimetres high may be obtained.

A special experiment was made to test the intensity of the light generated by this flame. Some chloride of silver,

after precipitation, was collected upon the surface of a piece of cardboard, and was put into a small camera, illuminated by the lamp of which we have been speaking. This film of chloride, after a few seconds, began to assume a violet tint, indicative of energetic reduction. The photogenic intensity of the light, according to M. Franck de Villechole, is much superior to the artificial light usually employed by photographers, as will be seen by the following.

The flame having been produced in a sheet-iron cage supporting a lens on one of its sides, the image from a glass positive was projected upon a sensitive plate. A cliché, enlarged to a quarter life size, was obtained in ten seconds. The same operation executed with a magnesium lamp burning two ribbons was less prompt and less successful, while the illuminating power was much more difficult to regulate. The lamp illuminating the camera was then placed two metres distant from an engraving, and without the assistance of lenses or reflectors a negative was secured in five seconds. Finally, a portrait was produced in about fourteen seconds, the model being placed about two metres from the lamp.

According, therefore, to those repeated experiments, the investigators estimate that the light is superior, so far as its photogenic power is concerned, to that of magnesium; that it is twice as energetic as the oxy-hydrogen lamp, and three times more actinic than the electric light. M. Stebbing has since experimented with this new lamp, and his results bear out those to which we have referred.

ERNEST LACAN.

#### ON THE PHOTOGRAPHIC TRANSPARENCY OF VARIOUS BODIES, AND ON THE PHOTOGRAPHIC EFFECTS OF METALLIC AND OTHER SPECTRA OBTAINED BY MEANS OF THE ELECTRIC SPARK.

BY W. A. MILLER, M.D., LL.D.\*

63. *Olefiant gas.*—Some difficulty is experienced in observing the spectrum of this gas, owing to the copious deposition of carbon which occurs immediately that a current of sparks is transmitted. The nature of the electrodes employed seems to exert considerable influence upon this decomposition. It is extremely intense when aluminum electrodes are used, but comparatively slight with gold. Observations made when gold electrodes were employed exhibited a spectrum which could not be distinguished from that of carbonic acid or of carbonic oxide.

64. *Marsh-gas.*—Sparks pass freely in this gas. The spectra obtained with gold and copper electrodes cannot be distinguished from those of the same metals in carbonic acid and carbonic oxide. A scanty separation of carbon occurs during the passage of the spark. This is particularly evident when copper electrodes are used, the bluish light of the metallic spark being frequently accompanied by reddish-yellow scintillations; the deposition of finely divided carbon upon the quartz plate on the side of the gas-tube impairs the intensity of the photograph.

65. *Cyanogen.*—A difficulty was experienced in this case also in obtaining intense photographs, particularly when silver electrodes were employed; a rapid deposition of a brown matter, probably paracyanogen, took place upon the interior of the tube. When copper electrodes were used, the light of the spark was sometimes of an intense green, at others of a pale blue. The photograph showed the particular lines due to carbon as well as those of nitrogen, and the special lines due to the metallic electrode employed.

66. *Sulphurous Acid.*—This gas offers unusual resistance to the passage of the electric sparks, the electrodes requiring to be brought very close to each other before the disruptive discharge passed freely. This difference in the power of different gases to modify the striking distance has already been examined by Dr. Faraday.† A strong

\* concluded from page 578.

† Philosophical Transactions, 1863, p. 103

spectrum was obtained with gold wires; it terminated abruptly at 113.5, a single spot of renewed action appearing at 143.0. This result is due, no doubt, to the absorbent action of the gas, which has been already shown, in a former section of this paper (18), to be one of the least diastinct of gaseous bodies. In this form of experiment the stratum of gas traversed by the rays before they entered the air amounted to about half an inch in thickness.

67. *Sulphuretted Hydrogen*.—This gas also offers considerable resistance to the passage of the electric spark. It is decomposed by the spark with deposition of sulphur. When gold electrodes are used, it furnishes lines resembling those of the same metal in air. With silver electrodes the gas was decomposed very rapidly, and no lines were produced beyond 113.5, the absorbent action of the gas being strongly manifested.

68. *Ammonia*.—Sparks pass in this gas as freely as in air; the spectrum of each metal is the same as in nitrogen; no new lines are visible in the photograph. Most of the atmospheric lines are distinct.

69. *Protoxide of Nitrogen*.—The electric sparks pass in this gas with much greater difficulty than in air. The spectrum appears to be the same as that produced in air, and no new lines are apparent in the photograph.

70. *Nitrogen*.—The spectrum of this gas, when gold or platinum electrodes are used, commences with a pale continuous spectrum, which slowly diminishes in intensity; this continuous spectrum appears to increase in intensity with the volatility of the metal, being well marked in the case of magnesium, sodium, and potassium; at about 151 it terminates abruptly. The spectrum of nitrogen is crossed between 96.5 and 100 by two strong double lines; it shows an indistinct line at 108.5, a strong one at 110.5, three feeble lines at 113.5, 118, and 122, a faint band at 138, and another at 150.

71. *Oxygen*.—This gas was obtained from black oxide of manganese heated with sulphuric acid. It gave, after purification by passing through a solution of caustic soda, lines identical with many of those obtained in atmospheric air. When the gas contained traces of carbonic acid the lines due to the compounds of carbon were distinctly visible in the impressed spectrum. With platinum electrodes and with pure oxygen, a feeble, nearly continuous spectrum extends to about 122.5; it also contains numerous lines extending as far as 142.5; beyond that, the impression is more feeble, terminating at about 156. The principal lines due to the gas are the following:—A broad line about 100, then two faint lines, beyond which, at 101.5, is a double line; a strong complex group at 103.5; a feebler one at 105.5; one rather stronger at 107.5; a double group of considerable strength at 112; another stronger at 114; between 116 and 119 is a group of six rather faint lines; after this there are no prominent lines until 138.2 and 141.5; at 153 is a strong compound line, and beyond this only the dotted lines of platinum are seen.

72. *Chlorine and Hydrochloric Acid* give spectra which can scarcely be distinguished one from the other. With platinum points these spectra terminate by an abrupt band at 156.5. Their most marked features are a strong compound band at 96.5, and one still more marked at 100; then two lines, of which the first at 103 is the stronger, followed by two others, of which the second at 108.5 is the stronger; several fainter lines follow these lines. A group of six between 126 and 133, the most marked of which is a broad band terminating at about 130. Several faint lines intervene between this and another broad band at 140, followed by several others less distinctly defined.

I attempted to obtain the spectra of iodine and bromine by employing a current of hydriodic and hydrobromic acid; but the results were not satisfactory. It is very difficult to maintain a steady current of sparks through these gases, and not easy to keep up a continuous current of the pure and dry gases, which are immediately decomposed by the passage of the electric spark, with extrication of dense fumes of iodine or of bromine.

## Correspondence.

### IMPROVED TRIPOD STAND.

DEAR SIR,—I received the NEWS this morning, and am glad Mr. Oakley has written to you on the subject of the "Improved Tripod Stand," because he has removed an impression from my mind which was an unjust one. He has not borrowed an idea from me, nor I from him.

He says in his last sentence, "The bolts in my stands have large heads, and under the fly-nut is fitted a large brass washer," &c. This proves his arrangement is not different from the old French tripod stand, though he may have improved it in some way. At any rate, it is quite different from mine, the lower or sliding portion of which consists of one solid piece of ash, one inch wide by three-quarters of an inch thick, instead of the double continuation between which his "bolts" must work; and in this difference (mine also being fixed by a screw pressing against the sliding part) consists my invention, or improvement, as it enables me to make my tripod lighter, stronger, and firmer. I have never seen Mr. Oakley's tripod, or I should not have troubled you on the subject.

I must, however, state that I prefer my revolving levelled block (which I think, thus applied, also new) to his ball and socket, because the latter would necessitate the re-levelling of the camera for each successive plate of a series in taking a large panorama, creating, probably, great inexactness; whereas, I must repeat, my camera once levelled properly, the block is *always* level, and the camera only requires to be turned by very slightly loosening a screw (between two dowells), which fixes the camera to the stand, and which is tightened again when the new point of view has been decided on.

The objections named by Mr. Oakley I have not found in practice, and it is impossible for the block to get out of order, while the ball and socket may; the former, I should say, being also much less expensive, and answering admirably.

Mr. Oakley has misconstrued the cause of my disappointment. I was not annoyed that any one had imitated my legs, but that any one claimed as copyright what I supposed to be mine, and which I wished should be *pro bono publico*, as I still desire, believing, as I do now, that my arrangement forms no part of Mr. Oakley's copyright.

I omitted to say that my tall legs are three feet five inches long, without the tripod head and block, altogether 1½ inch above them, and that they extend to exactly seven feet to the centre of the grey glass of a 10×8 horizontal camera when set up.

I think your remark that my legs "admit of more extension" than Mr. Oakley's will be found correct—*e.g.*, a four-foot leg may be extended, perhaps, to about a foot more than his No. 2.

I shall not trouble you any further on the subject, and only hope that the discussion may have done some good.—I remain, dear sir, yours faithfully,

Catherston Manor, Dorset, Dec. 5th. T. H. PARKYNS.

PS.—It is important that the two dowells act so as to make the block and the camera really one (except for convenience in packing), the fixing screw passing from under the wooden tripod head *through the block*, into the bottom board of the camera.—T. H. P.

### LIFE-SIZE PORTRAITS.

SIR,—I have to thank you for the note appended to my letter in your last issue. But the portrait alluded to by Mr. E. M. Ward and Mr. S. C. Hall was in truth the life-size of the lady represented, viz., 7½ inches from top of forehead to bottom of chin.

I think the general disfavour with which the life-sized heads shown in the Crawshaw competition have been received is due to Mr. Crawshaw's having drawn the hard and fast line as to size in inches, instead of varying life size, leaving

it then to the judges' discretion. We might then have had life-size pictures from a child with head of 6 or 6½ inches, to a man with head of 8 inches. As it was, many of the female heads were over average life-size, and therefore bore the appearance of exaggeration.—Faithfully yours,

H. STUART WORTLEY.

#### KENNETT'S GELATINE PELLICLE.

SIR,—In your issue of the 20th of November Mr. Aldridge complained that Mr. Kennett was out of pocket by what he called "his discovery," and in your issue of the 27th I ventured to point out that there was no "discovery" as regards Mr. Kennett in the making of a gelatine emulsion, and that as Mr. Kennett had speculated in a patent he must abide the results of his speculation, and I concluded my letter with the following paragraph:—"He is indebted to other workers for the emulsion itself, and, in my opinion, should have considered this before attempting to take a patent. That the patent itself is not sound is no argument one way or the other." In your issue of the 4th December Mr. Kennett attacks my letter, and I now propose to answer his attack. He asks me to name for the information of your readers the person to whom he is indebted for the process he has patented, and he further goes on to intimate that I have accused him of stealing the brains of those persons for his own benefit.

I am bound, therefore, in self defence to give chapter and verse for every statement I made in my former letter. In order that you may see how completely Mr. Kennett has stolen the brains of other persons for his own benefit, I will ask you to print in columns side by side the following extracts from the photographic press and Mr. Kennett's own specification, which latter I beg your readers to bear in mind is dated the 20th November, 1873.

*Published by Dr. R. L. Maddox, on the 8th Sept., 1871, and again published on the 8th Aug., 1873.*

Thirty grains of Nelson's gelatine were washed in cold water, then left to swell for several hours, when all the water was poured off and the gelatine set in a wide-mouthed bottle, with the addition of four drachms of pure water and two small drops of aqua regia, and then placed in a basin of hot water for solution. Eight grains of bromide of cadmium dissolved in half a drachm of pure water were now added, and the solution stirred gently. Fifteen grains of nitrate of silver were next dissolved in half a drachm of water in a test tube, and the whole taken into the dark room, when the latter was added to the former slowly, stirring the mixture the whole time. This gave a fine milky emulsion, and was left for a little while to settle.

*Extract from Mr. Kennett's Specification, 20th Nov., 1873, No. 3782.*

My said improved substance or compound consists essentially of gelatine or gelatinous matter in combination with nitrate of silver and with bromide of potassium, bromide of cadmium, bromide of ammonium, or with the chloride or the iodide of either of these salts in combination with either of the bromides above specified. In making the said compound I prefer to employ the following materials and process: that is to say, I place in a dish or pan of porcelain or other suitable material about one pound of the substance known as Nelson's gelatine, or other suitable gelatinous matter, to which I add about one hundred ounces of distilled water. This mixture of gelatine and water is allowed to stand for about three hours to soften the gelatine, and is then heated by a hot water bath or otherwise until the gelatine is thoroughly dissolved. I then add to the mixture or compound about eight and a quarter ounces of the bromide of potassium dissolved in water, and which must be thoroughly incorporated with the gelatine by stirring. I then incorporate with the said compound, while stirring the same, eleven and one-half ounces of nitrate of silver dissolved in water. The whole of the above operations must be effected while the gelatine is hot.

Note how closely Mr. Kennett follows Dr. Maddox, even to the order in which the materials are added, and the "stirring." I think the above two extracts are sufficient answer to Mr. Kennett as to whose brains he has stolen with regard to the making of a gelatine emulsion; but Mr. Kennett goes further in his specification than the mere making of an emulsion, for, as I pointed out in my original letter, he patents the drying of the gelatine and reducing it to a solid substance easy of carriage. We will now see from whose brains he has stolen *this* idea.

*Published on the 14th Nov., 1873, by Mr. J. Johnston.*

To make the gelatine-bromide emulsion, put half the gelatine to be used into one vessel, and the other half into another. Now pour as much bromide of cadmium solution into one of the vessels, and as much nitrate of silver solution (measured) into the other, as will cover the gelatine.

When the gelatine is swelled sufficiently, pour the solution off, and measure; by that means the quantity of bromide and silver taken up by the gelatine will be ascertained. Keep the bromide in excess of its equivalent of silver by adding bromide solution if required. Heat both the quantities of gelatine until dissolved, then mix, stirring with a glass rod. Let it stand till cold, cut in slices with a piece of thin glass, and wash in distilled water to remove the excess of bromide.

Note here, again, how closely Mr. Kennett follows Mr. Johnston's words. Does this make it sufficiently clear to your readers from whose brains the idea was stolen of reducing the emulsion to a solid compound, thus rendering it easy of carriage between manufacturer and customer?

At the end of Mr. Kennett's patent the following is the claim he makes:—"I claim a substance or compound for forming photographic emulsions, which, when prepared in a dry or solid condition as herein set forth, will remain perfectly good and fit for use for any required time."

Now, sir, the extracts you have printed side by side arc, I think you will admit, ample evidence in proof that Mr. Kennett was indebted for the emulsion itself, and the idea of reducing it to a solid material, to the labours of others. When, then, Mr. S. S. Young talks of my having brought a vague charge, and of the antipathy of a rival manufacturer, he talks of what he does not understand. The charge is now no longer vague, and as the claim made in the patent is for the "substance prepared in a solid condition," the method of doing which I have shown was published seven days before the date of Mr. Kennett's patent, the whole patent is worthless, and any rival manufacturer is at liberty to make dried gelatine pellicle, if anyone thinks it worth while.

Mr. Kennett, in his letter last week, says he has numbers of letters thanking him for placing the process in the writers' hands, and on this I desire to say a few words. Mr. Kennett has done exactly the reverse. The processes were placed in the hands of the public through the press by Dr. Maddox and Mr. Johnston, and Mr. Kennett endeavoured to prevent their public use by patenting them.

Now I freely admit the great value of patents to protect inventions; in photography they have done great good, for it would have been impossible for the capital to have been found to bring the carbon printing and Woodburytype to their present successful development had they not been protected; but when I find anyone in the position of Mr. Kennett, whose name has been hitherto unknown in photography, going to the Patent Office and taking a patent for, possibly, valuable commercial matter which had attracted his attention in the press the week before (for bear in mind Mr. Johnson's paper was published November 14th, and Mr. Kennett's patent taken November 20th), and thus endeavouring to seal up a process that is really public property, I strongly object, and I call on the photographic brotherhood to say whether such conduct is not worthy of condemnation. My note-book shows that on Monday, November 17th, I prepared, and brought into a solid and dry condition, a lot of gelatine emulsion for experimental purposes—some of it has remained good to this day; and it would be absurd for a patent, dated November 20th, to prevent anyone doing the same.

In fact, the process is perfectly open, and the Liverpool, or any other Company, are free to make pellicle without let or hindrance, Messrs. Kennett and Aldridge notwithstanding.—Yours, &c.,

A WORKER.

At this stage of the process the said compound or emulsion will contain free bromide of potassium, and nitrate of potassa, which must be eliminated, and which I eliminate as follows:—I pour the emulsion into glass or porcelain dishes to the depth of about a quarter of an inch, and let it stand long enough to become cold. I then remove it from the dishes, and cut it in small strips and wash it with many changes of water, or in running water, until the free salts are all dissolved out. I then dry or desiccate the substance or compound to render it capable of preservation for any length of time, and therefore fully accomplish the object of my invention.

DEAR SIR,—In your journal of Nov. 20th appeared a short letter of mine, in confirmation of that of a correspondent signing himself "A Portrait Painter." In that letter I ventured to give Mr. Kennett some advice, for which I am responsible, and which, of course, my friend Mr. K. is at liberty to follow or not, as he thinks best. In the NEWS of last week appeared a letter signed "A Dry Plate," and containing so much personal abuse of myself, that I cannot allow it wholly to pass, at the same time that I must decline to enter into a controversy of the sort with an anonymous writer. As "A Dry Plate" appears to have such strong feelings on the subject, let him back them up with his name: I shall then know how to answer him. I dislike stabbing in the dark, and have an equal antipathy to fencing with a shadow.

"Give me but light, and let me see my foes,  
I'll bravely fight, though Jove himself oppose."

There is one assertion, however, in the letter of "A Dry Plate" that I cannot pass without contradiction. Your correspondent affects to be very particular about the date of my previous letters, and then goes on to state that I introduced the pellicle six months ago. Now, as Mr. Kennett read a paper, and exhibited both negatives and prints at the Technical Exhibition of Nov., 1873, notices of his preparation having previously appeared in the journals, it is evident that "A Dry Plate" has allowed his imagination to totally overpower his memory, or else is in the habit of writing what first comes into his fingers.—Yours truly,

R. W. ALDRIDGE.

## Proceedings of Societies.

### PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE usual monthly meeting was held in Conduit Street on the evening of Tuesday, December 8th, Mr. J. Spiller, F.C.S., in the chair. The minutes of a previous meeting having been read and confirmed, the following gentlemen were elected members of the Society: Messrs. E. A. Coe, Joseph Gale, and W. Pitt.

The CHAIRMAN announced that as all the officers would go out of office, it would be necessary for members next month to nominate a completely new staff, President, Vice-Presidents, all the members of Council, and Treasurer, for election according to the rules at the annual meeting in February.

Mr. HUGHES asked under what rules the Council was proceeding. The rules brought forward during the year had never had the sanction of the Society; he himself had protested against them being passed at a small meeting in the dog days, and at the annual meeting they would require considerable revision.

The SECRETARY, referring to the minute-book, said that the laws had been duly passed, Mr. Hughes' motion to postpone their adoption did not meet with a seconder. Until the annual meeting—when modifications might be made—the Council could act upon no rules but those then passed.

Mr. HART made a few remarks on the want of some proper place to keep the books and pictures of the Society.

Mr. MUNDY's paper on "Photography in New Zealand" was then read, and was followed by an exhibition by means of the siopticon of many fine New Zealand views, especially illustrating the extensive geyser system. Mr. Mundy described the views, and Messrs. Bool took charge of the lanterns.

The proceedings then terminated.

### EDINBURGH PHOTOGRAPHIC SOCIETY.

THE second ordinary meeting of the session was held in 5, St. Andrew Square, on the evening of Wednesday, the 2nd inst., the President, Dr. THOMSON, R.N., in the chair.

The minutes of the previous meeting were read and confirmed, and the following gentlemen were admitted ordinary members:—Messrs. James Steele, W. Hurin, W. Haldane, John Dick, R. C. Paterson, Andrew Smart, John A. Leechman, James Mill, and Ex-Bailie Wilson.

This was the most largely attended of any ordinary meeting since the formation of the Society.

The SECRETARY stated that a number of members had intimated their intention of contributing photographs for distribution by lot amongst the members present at each meeting throughout

the session, in the manner found so successful two years ago; and laid on the table some fifteen, for that night, the joint contribution of himself and the President.

The CORRESPONDING SECRETARY laid on the table the first three numbers of the Journal of the Belgian Photographic Association, and stated that he had had several communications from the Secretary of that young society. He said that from the journals it would be seen that they were doing the work of the society in a very workman-like way, and he had no doubt that they would make it a great success. An interesting feature in their journal was the giving in each number a specimen print by one or other of the various carbon processes. The specimen in No. 3, a *phototypie*, was a little gem that did credit both to the photographer and the printer. The same number, he might say, contained a *multum in parvo* resumé of carbon printing, from Mungo Ponton downwards, from which, as Edinburgh men, they would be glad to see that it was acknowledged that the real foundation of permanent printing was laid in their own city.

The CORRESPONDING SECRETARY was instructed to convey the thanks of the meeting to the Belgian Photographic Association, and to congratulate the members on the success which had already attended their efforts in the formation of the society.

Mr. W. T. BASHFORD then read a paper, "The Spirit of the Journals" (see page 591). Before doing so, however, he stated that it was not until he saw the billet that he knew so much work had been laid upon him, as he understood that another gentleman had undertaken the work. As it would not do for one who had been honoured by a seat at the council board to set a bad example, he had done the best he could, although, as he had been called on to distil the "Spirit of the Journals" with only a few hours allowed for fermentation, they must not expect anything but an unsatisfactory distillate.

The President, Mr. W. Neilson, and others, complimented Mr. Bashford on his paper, and hoped he would allow himself to be elected permanent distiller to the Society, assuring him that, judging by the quality of the spirit produced, the fermentation had been complete.

Dr. DICKSON wished to call attention to the method of seeing stereoscopically without a telescope, noticed by Mr. Bashford. He said that Dr. Nicol had taught him to do this more than fifteen years ago, and for some time he had amused himself by examining the pictures in shop windows in that way. He was sorry to say, however, that a rather unexpected and disagreeable result had followed the practice—a serious case of astigmatism, from which he still continued to suffer. In fact, he said, he had ever since that time seen all objects double, unless when he corrected the fault in his eye by suitable lenses. It was the opinion of oculists generally that astigmatism was always congenital, and never made its appearance accidentally; but his case was a very striking proof to the contrary. He could not, of course, say that the astigmatism had been caused by the squinting, but he thought it right to mention the circumstance, as it might possibly attract the attention of those interested in the subject.

Mr. ROSS agreed with almost every word that Mr. Bashford had said, but especially with his remarks regarding the so-called Rembrandt effects. He was sure that if that painter were to revisit the earth, he would be ashamed to bear his name connected with such trash. He was sure that the old style of lighting was in every way much better.

Mr. BASHFORD then read another paper on "An Unsuspected Cause of Spots on Carte-de-Visite and Cabinet Photographs" (see page 592), and handed round a number of cabinet-mounts, on which, although there was nothing visible to the naked eye, the point of the finger, when rubbed across the surface, became coated with a dark but shining metallic bronze.

Mr. TURNBULL then read a paper on "The Photometric Value of Different Lights Used in the Lantern" (see page 589), and exhibited an improved lamp for burning paraffin oil, showing at the same time a number of pictures by means of a lantern lighted with the lamp. The lamp is an improved form of one exhibited before the Society last year, and is constructed on the principle of that used in the siopticon, the object being, by the addition of a third wick, to get rid of the shadow which passes perpendicularly across the screen, and to give a whiter and more brilliant light than the siopticon lamp.

Dr. NICOL was glad that Mr. Turnbull still continued his experiments with a determination to improve the lantern lamp. Although he did not hope that it would ever equal the lime light for the purpose, there were many cases where it would be really of more value. Many a pleasant evening could be spent with a few friends over a number of pictures in circumstances

where the latter was altogether out of the question, but in which such an arrangement as Mr. Turnbull was labouring to perfect would be invaluable.

Mr. Ross could not say that he was at all satisfied with the performance of the lamp; the light was, he thought, a little better, but there was a want of steadiness which was very objectionable, and the images of the three flames on the screen were really worse than the shadow from the original lamp. He must say he liked the scription better.

Mr. TURNBULL said, in reply, that the lamp had been shown to very great disadvantage. He discovered only when he came into the room that the lantern would not admit of the lamp being turned to the angle at which the shadow was got rid of, and that the lens would not screw into the flange, and had to be held in the hand. From exhaustive experiments, he knew that the lamp was much superior to that with the double wick, both in colour and brightness, and should take an early opportunity of showing such to be the case to the satisfaction of the members.

Votes of thanks were given to Mr. Bashford, Mr. Turnbull, and the donors of the pictures distributed, and the meeting adjourned.

The Annual Dinner took place in the Café Royal on the evening of Wednesday, the 15th ult., the President, Dr. Thomson, in the chair, and Dr. John Nicol (in the absence of the Vice-presidents) oronprier. Mr. William Anderson, a member of the society, who had recently succeeded Mr. Nieve as proprietor of the hotel, served up a most capital dinner, which was done ample justice to, and the members present, of whom there were a large number, spent a very pleasant evening. After the usual loyal and patriotic toasts had been duly honoured, several connected with photography and kindred subjects were heartily responded to. The intervals were filled up with songs, recitations, and pleasant conversation, which was kept up till a late hour, when the party separated with a strong expression of opinion that such meetings might be very profitably held more than once a year.

#### WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

The second general meeting of the above Society was held on the 30th ult., at Leuchter's Rooms, Iregate, Bradford, Mr. J. W. Gough in the chair.

The minutes of the last meeting having been read, it was decided to hold the annual meetings of the Society in November of each year, and to constitute the existing meeting the first of the session 1874-5.

The officers were therefore re-elected as follows:—*President*—Mr. J. W. Gough. *Treasurer*—Mr. Rogerson. *Secretaries*—Messrs. Crosthwaite and Holgate. *Committee*—Messrs. Greaves, Rogerson, Sacks, and Barrow, with power to add three additional members to their number.

The meeting then devoted its attention to drawing up a code of bye-laws, which will be printed, and a copy issued to each member on his entrance.

The arrangements for the admission of new members first claimed attention, and led to a somewhat animated discussion. It was finally agreed that they be admitted by ballot, and that one black ball in five shall exclude, the ballot to take place at the meeting following that at which the member shall have been proposed.

The CHAIRMAN suggested, and it was agreed, that in the case of any member committing any immoral or illegal offence, it was desirable that there should exist in the members' hands the power to expel any such member from the Society. In order to effect this in the least objectionable manner, any member having any such complaint against any other member shall place a written statement in the question box; it shall be discussed at the next general meeting, and a majority of two-thirds shall be sufficient to expel.

The question of election of officers also gave rise to considerable expression of opinion, and after much discussion it was decided that three of the committee shall retire annually in rotation, and shall not be eligible for re-election for one year; that the President shall be elected annually, but he shall be eligible for re-election for one year, but shall not hold office for more than two years successively.

The CHAIRMAN proposed that the Society should hold an annual exhibition of photographic productions, and that prizes should be offered for competition; that a competent and acknowledged art-critic should be employed to report on the artistic qualities of the works exhibited; and a committee of gentlemen of known photographic ability should report on their merit photographically.

Mr. WORMALD (Leeds) entirely agreed with the Chairman's

remark, but considered it necessary that each exhibitor should be required to furnish a written guarantee that his exhibited work was his own *bonâ fide* production.

The CHAIRMAN considered that was a necessary requisition from each competitor.

After some further discussion it was decided to give the matter consideration at a future meeting.

The Secretary then received subscriptions from between twenty and thirty members, and over twenty new members were admitted.

Messrs. G. W. Simpson, of the NEWS, and J. Traill Taylor, of *The British Journal*, were unanimously elected honorary members; and, after a few further observations, the meeting adjourned.

The next ordinary meeting will be held on the 28th inst., at 7.30, in the same rooms, when a lantern exhibition will be given by Mr. Manley, of Brighouse, at which entertainment all gentlemen interested in photographic matters will receive a hearty welcome.

### Talk in the Studio.

KENNETT'S PELLICLE.—Mr. Kennott, referring to an answer to a correspondent in our last, mentions that the pellicle should be placed in cold water to soak, and in half-an-hour place the bottle containing it in hot water. The printed instructions are precise and detailed in their guidance.

M. LAMBERT'S MODE OF FINISHING NEGATIVES.—Mr. S. Fry informs us that he has tried the mode of finishing negatives described in our article on Lambertype, and finds it admirable in result, and very easy in application.

THE PRICE OF ENLARGEMENTS.—A curious case was heard at the Shoreditch County Court on the 1st inst., which arose from the defendant refusing to pay a balance which the plaintiff alleged was due to him on account of work done. The plaintiff was a Mr. W. W. Roberts, of 195, Kingsland Road, and the defendant was Mr. W. Perrin, photographer, of 146, Kingsland-Road. It appears from what the plaintiff stated that Mr. Perrin employed him to enlarge three pictures, for which he agreed to pay him 8s. each, and that he had paid 10s. on account. This summons was taken out for the purpose of gaining the balance of 14s. The defendant stated that on Saturday, the 26th of September, he took three small pictures to the plaintiff, and asked him, as he was very ill, if he, the plaintiff, would enlarge them, which he agreed to do for 3s. each. The defendant went over for the pictures, and put down half-a-sovereign, expecting the plaintiff to give him the 1s. change, instead of which he said defendant agreed to pay him 8s. each for the pictures and after some further dispute plaintiff said he would give a receipt, which he did by writing on a piece of paper, "Received on account, 10s." He did not hear any more from plaintiff for some time, until he sent him a bill demanding the 14s. balance, which he refused to pay. The defendant called Mr. W. Munyard, who stated that 2s. each would have been a fair price, and referred the Judge to the trade advertisements in the PHOTOGRAPHIC NEWS, to show that what he stated was correct. The Judge finished the case by deciding it in favour of the defendant.—*Hackney Press*.

FIRE IN A STUDIO IN MANCHESTER.—Some days ago a fire broke out about half-past six on the premises occupied by Mr. Baum, photographer, St. Ann's Square, after they had been closed for the night. On the arrival of the firemen and engines, under Mr. Tozer, flames were bursting out of the windows, and it was found that they had made considerable havoc on the top floor. Two jets of water were brought into play, and after an hour's work the fire was extinguished, but it was deemed necessary to leave a fireman with a hand-pump in charge of the premises for the night. In addition to the damage done in Mr. Baum's rooms, the other parts of the buildings and their contents suffered slightly from the copious deluge of water. The origin of the fire is unknown. While the brigade were engaged in St. Ann's Square, they received notice of a third fire at Messrs. Capes and Dunn's salo room, Albert Square. Mr. Tozer despatched three of his men to the place, and they found a beam on the ground floor in flames, which they soon extinguished. The cause of the fire was the beam's proximity to the fireplace.

EXCHANGE OF UMBRELLAS.—At the last meeting of the Photographic Society, an exchange of umbrellas was unintentionally made in the council room. Any gentleman whose umbrella was taken will hear of it on writing to the Editor of this Journal.

## To Correspondents.

**THE YEAR-BOOK OF PHOTOGRAPHY FOR 1875.**—We have again to thank many correspondents for valuable and interesting contributions to our forthcoming Annual. As the time has arrived when all copy *must* pass into the printer's hands in order to avoid disappointing delays, we would urge those friends who have not yet sent in their contributions, to oblige us by forwarding them at once.

**CAPTAIN STRETTON.**—An ordinary portrait lens with central stop will give you straight lines; but you must remember that a large angle always involves the use of a small stop, and consequent long exposure. To effect what you require, you must necessarily experiment to find the best compromise between length of exposure and extent of angle. You will find a decided difference between keeping the plate for a time and then exposing, and exposing first and then keeping the plate for the same time. In the latter case, you will, under ordinary circumstances, find the imago on a wet plate gradually disappear during long keeping. The negatives duly arrived (one broken), and well illustrate your remarks.

**APPRECIATOR.**—The best commercial enlargements are made in various ways; but, as a rule, all the best work at the present day is by processes resembling each other. It is generally recognized now that a better result is obtained from an enlarged negative than from a developed enlargement on paper. A direct enlargement by the solar camera on paper is probably as fine as anything which can be produced; but this requires continuous strong sunlight during an hour or two, and this cannot be secured during winter in this country. Enlarged collodion prints transferred to paper are often very fine; but, whilst possessing great delicacy, they often lack vigour. A good transparency from a good negative will generally give a good enlarged negative, from which, as a rule, the best results can be produced. The enlargements issued by the Autotype Company are produced in this way, the transparency being made on carbon tissue. 2. There is no book on the subject of enlargement. 3. In developing the large plates to which we referred, M. Lambert had a quart jug full of the iron solution, and by one skillful quick turn of the wrist threw the contents so as to cover the plate at once. 4. Wooden baths or dishes for use with silver solutions, or any photographic solutions, should be first thoroughly varnished two or three times, finishing either with shellac varnish, or a mixture of collodion and linseed oil.

**H. SYMONDS.**—We do not know of any agent for Obernetter's paper in this country. We believe that Mr. Bruce obtains it direct from the maker, and you can probably do the same by writing to Herr Obernetter, photographer, Munich.

**NO NAME (Whitehaven).**—A correspondent sends us a letter referring to one of the secret processes advertised for sale, and pointing out that the alleged secret has really been published in the journals. Possibly it has more than once, as have many alleged secrets. It is also probable that such processes have been worked out, verified, or modified, and some systematic or trustworthy form given to them by the advertisers; and this is often worth something, if not worth all the amount charged. One of the most successful and skillful English photographers once wrote: "I do not believe that there is a secret in connection with photography in existence which has not been published in the News;" but, he added, it was often a secret to the reader which out of many processes to select. Thus, in reference to enlarging, enamelling, pre-lighting, keeping the bath in order, &c., probably all the information in existence is to be found in the News; but the vendors of secrets are able often to say: "Very true; but, having tried the whole, I can sell the special process which is most efficient, and save you the trouble of trying a dozen to find which is the best." At any rate, in purchasing secrets the buyer must remember the motto,  *caveat emptor*. A "pig in a poke" may be worth all the money asked. The purchaser, of course, takes a risk, and if he is content to take the risk beforehand, we do not think it wise to complain afterwards.

**A RUBIE.**—Blisters in albumenized prints arise from various causes. If you have read the PHOTOGRAPHIC NEWS carefully during the past year, you will have found it the subject of frequent consideration. As a rule, the most highly albumenized papers are most subject to this defect. We can only here briefly indicate some of the causes and remedies. Floating the paper a short time on the silver bath, so that the film of albumen is not coagulated right through is a frequent cause; the use of a decidedly alkaline toning bath is an occasional cause; the transference of the print from the dense solution of hyposulphite into plain water, is a frequent cause. Floating sufficiently long on the silver bath is a remedy; immersing the print in strong alcohol is a remedy; the use of less highly albumenized paper is a remedy; the use of a neutral toning bath a remedy; immersing the print in a solution of salt and water somewhat less dense than this hypo bath after fixing before immersing in plain water is a remedy, each of the remedies meeting some special condition. You will find some information on the subject in our forthcoming YEAR BOOK.

1874.—The "Instructions" you have purchased seem to be meagre enough; but such hints as there are seem to be pretty good. 2. There is nothing better for mounting enamelled prints than strong hot glue; but the glue must be good, used very hot, and with as little water as possible. So used it is generally very tenacious. In some cases the print is mounted on a soft thick paper, previous to mounting on the card, and this is efficient and effective. 3. We have published full details as to producing enamelled surfaces several times. The best hint we can give you, is to recommend perseverance and care. The fact that you succeed sometimes, and fail other times suggests rather that you as yet lack experience, than that your method is defective.

**S. S. YOUNG.**—There are three associations of photographers in London. The Photographic Society, often called the Parent Society, from being the earliest; the South London Photographic Society, and the Amateur Photographic Association. In the first, the subscription is a guinea annually, with a guinea entrance fee. The meetings are held monthly during eight months of the year; it publishes a journal of proceedings during those months, which members receive, and it holds exhibitions annually, to which members are admitted. The South London subscription is half a guinea annually, it also holds meetings and distributes presentation prints. The Amateur Photographic Association holds no meetings, and publishes no journals: its subscription is a guinea per annum, for which certain prints are received. You will find further details of this in the advertising pages of our YEAR-BOOK. In the two first, you must be proposed and seconded by members, before election. We shall have pleasure in aiding you when you have made your selection.

**F. H. WORSLEY BENISON.**—The papers have been forwarded. you will find the article is on his general mode of printing on collodio-chloride paper. The black tones depend on the conditions of deep toning described in our last.

**H. H. ANDREWS.**—The muffle used in enamelling is made of fire clay. It is something like a draining tile closed up at one end, and with a flat bottom. It is placed in the furnace, and admits of fire being placed all round it—top, bottom, and sides—and so forming a chamber uniformly heated. It is, of course, open in front to permit the enamel to be introduced for burning. The muffle itself is not necessarily a costly thing; but you must also have a good and suitable furnace. A strong, steady, and controllable heat is of vital importance in firing enamels. There are many difficulties to overcome, and much experience to be gained—even with good appliances—in order to produce the highest results, and we fear that little good will be effected by anything of a makeshift character.

**H. S.**—You may use a view lens for the purpose, but the exposure will be much increased. We should prefer a half or whole-plate portrait lens under the circumstances.

**A SUBSCRIBER.**—Wherever a formula instructs you to take so many parts, it leaves you at perfect liberty to interpret the word "parts" by grains, or drachms, or ounces, &c., just as you may require to make a small or a large quantity. For instance, in the formula you mention, suppose you take the parts as drachms: you will have 100 drachms or 12½ ounces of alcohol, and the same quantity of lac, and four ounces each of resin and turpentine. We may remark in passing that the proportion of lac seems to us to be very excessive. 2. It depends upon whether you use the common carbonate of soda, containing in its composition ten equivalents of water, or the purer and drier bicarbonate of soda. If you use the common commercial carbonate of soda, you may add 46 grains to each ounce of the solution. About 37 would serve, but it is better to use it a little in excess. Of the drier bicarbonate about 20 grains to each ounce.

**BRIGHTON.**—In the plan of which you send us diagram you will find it best to place the background at the south end marked D, slightly slanting towards the window.

**J. TURNLEY.**—Thanks. Washing prints in water containing carbonates or chlorides prior to toning is very apt to produce a white powder film on the surface of the print, which, if left undisturbed, is apt to interfere with toning. The tendency to this white deposit is increased by allowing the prints to rest soaking in the water. It may be prevented by using distilled water for the first washing, to remove free nitrate from the surface. Its formation may be checked by giving a hasty rinse, keeping the prints in motion instead of allowing them to remain at rest, soaking in the water. We generally consider a hasty rinse sufficient. A clean sponge is the best for removing such deposit when it is present. All the prints sent have very good qualities; they are clean, delicate, and brilliant, and without technical bluish. No. 3 is the best; but in vignette work a portion of a chair-back is better not shown. In No. 1, the points of the chair-back appear to start from each shoulder. These minor defects are the more apparent, because the work generally is of high-class character. Your lens does not give quite sufficient depth of focus without a somewhat smaller stop. In Nos. 1 and 2 the hair rapidly runs out of focus.

Several Correspondents in our next.

## The Photographic News, December 18, 1874.

### PHOTOGRAPHY IN AND OUT OF THE STUDIO.

WHY THE SUN'S DISC APPEARS LARGER ON THE HORIZON—  
PUBLISHING PAINTINGS BY MEANS OF PHOTOGRAPHY—  
MR. THOMSON'S EASTERN PICTURES—THE SUN'S RAYS  
IN WATER.

*Why the Sun's Disc appears Larger on the Horizon.*—The Transit of Venus week reminds us of an incident relating to photo-astronomy which may be interesting to those even who do not make the heavenly bodies their especial study. "How large is the apparent size of the sun or the moon?" is a question frequently asked. Some will say that the sun is about the size of a dinner plate, and when they hold the latter in their hands by way of instituting a comparison, they find that it would have been far better to have likened it to half-a-crown. "But then, as the sun begins to set, how much larger it grows!" someone remarks; whereupon the observer in question is generally informed that while the fiery disk *appears* larger to the eye, it is not so in reality. Now it is just upon this point that we desire to make a remark, for we wish to explain why the disk of the sun appears to some extent larger when the luminary sets. It is in some measure, then, because it *is* larger, and we well recollect, on the occasion of an eclipse of the sun some years ago (in 1862, we think it was) when, after a series of views of the sun's disk had been taken during the afternoon, a final plate was afterwards secured as the big sun was verging on the horizon. And behold! when the image was developed and compared with those taken earlier in the day, the difference in diameter was most marked. The limb of the sun was scarcely so sharply defined as in the case of the photographs taken when the luminary was high in the heavens, but still the outline was as perfectly clear, and the circumference a much larger one than that of the other pictures.

*Publishing Paintings by Means of Photography.*—Unlike France, Germany, and elsewhere, we have a way of regarding photographs of paintings with anything but a favourable eye. Suspicion and distrust generally attach to the possession of such an object, and it is usually understood to be a piracy, or something of the sort, that has not been honestly come by. Indeed, the photographer is very often put down in this country as the natural enemy of painters, and we fear many of the latter, notwithstanding their occasional weak protestations to the contrary, and the aid that each and every one of them draws from our art, do not look upon the works of the camera with favour. The pictures one sees of the Paris *Salon*, and those that come to us from Germany through the medium of the Berlin Photographie Publishing Company, prove the great use which the French and Germans, on the other hand, make of the photographer's art, and what profitable business may be done by having recourse to this cheap mode of publishing artists' work. When a painting is very popular (say as in the case of Miss Thompson's "Roll Call"), it may be better, perhaps, to pay the artist a good round sum for the copyright, and have the picture engraved; but for one of this kind, there are thousands of others of first-class excellence and acknowledged beauty, of which many people would be happy to purchase copies, but for which publishers would not give twenty pounds for the right of engraving; for this latter process itself may stand them in a thousand pounds or more, and one must needs sell many copies to get back the first expenses of engraving, copyright, and cost of printing, let alone the question of profit. Such paintings as we have alluded to are, therefore, never copied or duplicated at all, and all the money coming to the artist is that paid to him for his picture in the first instance. Thus both the artist and the public are losers, for the latter would gladly purchase copies in moderation, at a remunerative price, which would probably result in a handsome fee to the artist. It

is easy to understand that a thousand copies might be sold at half-a-guinea apiece, while a market would be altogether wanting for the same or double the number of pictures at five guineas. Photography stepping in here affords a cheap method of engraving, which is so far profitable to the artist that it creates a demand for his work that did not before exist. But many people will say, Photographing a picture makes it common. This is an objection which is easily met. Photographs properly produced, on a handsome scale, and printed tastily in an appropriate pigment, would be for the most part quite as agreeable to the eye as engravings, and would be as permanent. Moreover, they would be an actual transcript of the painter's work, for the engraver, however much of an artist he himself may be, often modifies effects very materially. Again, while for an artist's reputation a picture cannot become too common, for the publisher's protection it would be as easy almost to detect copies of a photograph well executed in pigments, as those of an engraving, and the laws of copyright would be as much guarded in the one case as in the other. We cannot help thinking therefore, that painters would do well to have their productions published by photography. The value of the original would only increase with the number of copies distributed, and many a modest picture, no doubt, would bring its author as much publishing as purchase money. In Paris, as soon as the Academy or *Salon* opens for the season, photographs are prepared of many of the pictures, and these copies are on sale in the Paris print shops and elsewhere, and realize large sums of money in their disposal. Some of the pictures are of very fleeting interest, and would certainly never pay a publisher to engrave, but they bring their authors notable sums in Royalties by being skilfully photographed. How long it will be before we in this country follow suit remains to be seen; but we think the action must come from the artists themselves, for at present publishers in this country do not sufficiently understand photography and its capabilities, and, consequently, are very unwilling to have much to do with it.

*Mr. Thomson's Eastern Pictures.*—We are glad to see that Mr. J. Thomson's "Book on the Straits of Malacca and China" has at last been published. Mr. Thomson's photographic work attracted so much attention by reason of its boldness and grand proportions, at one of the recent exhibitions of the Photographic Society, that it is gratifying to know that the sketches have been made good use of in the book we mention. In a book of travels where peculiar customs and people are described, there is nothing so welcome as well-executed pictures to illustrate the text. As Mr. Thomson took his camera with him wherever he went, and as he passed through some of the most untravelled portions of the East, the pictures he has brought home are exceedingly valuable and interesting. A series of pictures such as he has collected during his ten years' absence from England gives most people a better idea of Eastern life and scenery than they could otherwise obtain short of going abroad. The illustrations in the book have been carefully engraved from the photographs of Mr. Thomson, and the sketches have been most satisfactorily treated. A literary contemporary praises some of them very highly. "We often hear," it says, "of the Chinese coolie, when emigration questions are discussed. Turn to page 14 of this book, and we discover the very man. There sits the patient coolie at his mid day repast, undisturbedly shovelling vermicelli with chopsticks into his mouth. So, too, we are introduced to Buddhist priests, glaring Canton shops, the deck of a junk as she gets under way, and many other Oriental scenes and characters, set before us with an accuracy that cannot err.

*The Sun's Rays in Water.*—A curious experiment has recently been made to ascertain how far the chemical rays of the sun can penetrate water. The research was conducted upon the Lake of Geneva, whose waters are among the clearest of the Swiss lakes, and the result has recently

been communicated to the Society of Natural Sciences in the Canton of Vaud by M. Forel. He found that the chemical action of the sun's rays was felt in the summer time at a depth of between forty and fifty metres. We are not aware of the nature of the sensitive compound employed by Mr. Forel in these experiments, but we hope shortly to learn more of the details.

### PHOTOGRAPHIC EXPERIENCES IN NEW ZEALAND.

BY D. L. MUNDY.\*

THE album of fifty views and the eight framed pictures, illustrative of the geographical, floral, and economic features of New Zealand, which I had the pleasure of showing at the recent Exhibition, form part of a larger series of about 250 plates taken by the wet process under difficulties of travel and climate, and not without some personal risk. They represent the work of four years, directed by the experience of a much longer residence in the colony, which is necessary in order to know how to travel this wild and mountainous country, as it is only at certain periods of the year one can venture on such journeys—for instance, crossing the New-Zealand Alps from the east to the west coast in the South Island; and, to show the difficulties I had to meet, I may mention that I was ten days camping on the banks of the Otiira river, during a heavy fall of snow, hail, and sleet, before I dare attempt to cross; it was so flooded with ice-cold water coming down from the Alps. I frequently had to ford one river many times, on one occasion up less than twenty-three times; sometimes we had to drive the horses into the rivers and swim them over, heading them to the most convenient landing, and then had to ride many miles wet to the skin before finding a convenient place for camping down for the night. At other times I had to depend on my gun for food; and on several occasions I was nearly eaten up by mosquitos and sand-flies. The views were mostly taken by camping out with one or, occasionally, two companions, and moving from place to place, occasionally by coasting-steamers or small cutters and schooners when visiting many of the out-of-the-way places on different parts of the coast; while my journeys inland were made with a couple of pack-horses to carry the baggage (photographic and otherwise), following beaten paths whenever I could find them, but at other times taking my way through Maori tracks, fords, and bush, crossing dangerous rivers and swamps, with native guides or mounted escort, when I was travelling into the interior of the North Island, furnished with credentials (written both in Maori and English) kindly given me by the Hon. Donald McLean, native Minister, as at that time, when at Lake Taupo, I was not safe from the rebel chief 'Ti Kooti, for whose head there was a reward of £5,000.

Some of the plates have historical value, as:—Poverty Bay, the first point seen by, and first landing place of, Captain Cook in 1769; Mercury Bay, where he observed the transit of Mercury, first found fresh water, unfurled the British colours, and claimed New Zealand in the name of King George the Third; Bishop Selwyn's first settlement (Waimate), Bay of Islands; Akaroa and Banks's peninsula on the east coast, where the British flag was first planted; in the Middle Island, Maori relics of various kinds; the scenes of the wars; and the festivities connected with the visit of H.R.H. the Duke of Edinburgh, in 1869. Other illustrations portray the machinery and huts of the gold diggers, the making of flax-ropes, hauling kauri timber out of the bush, and shipping the same, road-making, and other industrial operations.

Natural history is represented by the *Apteryx* (or Kiwi of the natives, the wingless bird of New Zealand) and the *Dinornis* or Great Moa skeletons in the Canterbury Museum, by rock sections, &c.; and Plate 58 represents an immense boulder of conglomerate, 41 feet in circumference and per-

fectly spherical, which is now lying on the beach at Hokianga, near the residence of Judge Maning (the author of "Old New Zealand, and the Pakcha Maori"), with whom I spent several very pleasant weeks. This remarkable geological phenomenon, if of glacial origin as is surmised, occurs now in the hottest part of the islands, namely the upper extremity of the North Island. Such boulders are to be found of every size, from the ounce hullet upwards; the small ones were used by the natives in their tribal wars for loading their guns. The tropical plants, Nekau palms, great fern trees, black and white pines, *Phormium tenax* (New Zealand flax), and the flora generally are shown in a variety of scenes and combined with every variety of landscape, their forms being accurately delineated, whilst one feels the more regret in being obliged to add that the magnificent colouring of the valleys and mountains cannot yet be reproduced by the help of photography.

A few native groups and Maori settlements, with figures and costumes, come within the branch of ethnology, the grand geographical and geological features of the country being dealt with in a special series of photographs, twenty-four in number, representing the hoiling geyser system of Roto Mahana and Lake Taupo, which extends for about 160 miles inland, near the centre of the North Island. Another series of 60 plates shows the fine range of mountains forming the backbone of the South Island, and known as the New-Zealand Alps. Mount Cook, the highest point in this chain, has an altitude of 13,200 feet (nearly as high as Mont Blanc). Arthur's Pass 5,000, and the Rolleston glacier being about 8,000 feet above the sea. When I crossed these mountains in February, 1858, I travelled a distance of nearly 200 miles from Christchurch, in Canterbury, on the east coast, to Hokatika, in Westland, on the west coast, and the same on my return journey; the snow-capped peaks and the gorgeous foliage of the virgin forests, showing the beautiful rata trees in their intense foliage one mass of crimson, growing up close to the very ice, are admitted by all travellers to be of surpassing beauty; these were seen to the greatest possible advantage, this being about the height of the New Zealand or antipodean summer.

My usual plan of proceeding was to erect an ordinary digger's tent, supported upon a couple of forked poles and well fastened down with guy-ropes; then from the ridge of the structure, suspending a square photographic tent made of buckintosh material, with black calico skirts resting on the ground and kept securely fixed with stones. In fine weather this supplementary operating tent was erected outside the ordinary dwelling; but at other times better protection was afforded by suspending it within the larger tent. A square window of yellow oiled silk, measuring about 18 inches in both dimensions, admitted enough light to work by, and was of course proof against fracture during my journeys. A pack-horse carried a couple of strong leather trunks slung from the saddle, in one of which the chemicals were packed, while the apparatus was placed in the other. The camera-legs, folded tent, and stereo-camera were carried aloft on the back of the animal, between the panniers, and the second horse had enough to carry in the shape of the ordinary impedimenta of a traveller. When disposed for work the two boxes were placed within the tent un-packed, and the dipping bath filled from the contents of two or three Holland's bottles holding the silver solution, secured until now by corks protected with india-rubber finger stalls. The top of each bottle was carefully tied over with a piece of cloth. I have never used stoppered bottles, preferring to carry collodion and solutions packed in this manner. I learnt this from a sad mishap I once had, when I lost nearly everything through using stoppered bottles. One of the empty trunks was used to support the dipping-bath and screen it from the light and dust whilst sensitizing, and the other formed a convenient table with a primitive stool in front, consisting of a wooden board 12 inches long by 4 inches wide supported upon a single leg. My developing dish was a square tin tray 6 inches deep, and measuring about 20 by 16 inches.

\* Read before the Photographic Society of London.

Besides the stereoscopic I carried a 12 by 10 Kinnear bellows camera. The optical instruments consisted of Ross's triplet for distant views (some of my Alpine views were taken by this lens; No. 167 shows the Alps forty miles away up the river-beds), while I used Dallmeyer's wide-angle rectilinear lens for closer studies. Some idea of the range and performance of the last-named instrument can be judged from Plates 117 and 133, where a palm tree 30 or, at most, 40 feet from the camera is seen with satisfactory definition, the distant ranges, four miles away, being likewise sharply focused. With a  $\frac{1}{4}$ -inch stop eight seconds was the ordinary exposure, and I never, as a rule, exceeded twelve seconds.

I may mention that it was found necessary in a dry climate to pass a moistened sponge once round the inside of the camera, and then to wash out the dark slide, so as to guard against the too rapid drying of the plate, and that thirty-five minutes was the longest interval that was allowed to elapse between the preparation and development of the negative. Three or four folds of moistened red blotting-paper applied to the back of the sensitized plate likewise assisted in preserving a moist film; to keep out light and dust the carrier was always enveloped in a black velvet bag. I should mention also that a very convenient dipper was made for me in the colony out of a flattened ribbon of pure silver, made in the usual form of the wire dippers, but with strengthening bands placed at intervals to give greater rigidity. Out of seventy plates exposed during one of my tours, it was only necessary in four instances to repeat the operation on account of misjudging the time, and the same number of negatives (four) were lost by fracture during transit. For developer I commonly used a 30-grain solution of the double sulphate of iron and ammonium, containing in addition half its weight of sugar, and intensified, when necessary, with pyrogallic acid and silver. All the plates were fixed with a dilute solution of cyanide of potassium, and then washed with water from a tin kettle holding about a gallon, which served me besides for making the tea and other culinary purposes. The collodion and varnishes were supplied to me by a well-known maker, and I had never any trouble with them. The glass baths furnished in my original outfit unfortunately got broken; and this mishap occasioned a delay of three months whilst another dipping-bath, made of porcelain, was being forwarded from Sydney. This I found far preferable; there was less danger of breakage, and I could always have a clean bath by changing the bottles holding the bath solutions.

Under favourable circumstances my kit was unpacked, mounted for use, and the 12 by 10 plates, besides the stereo-negatives, taken in the space of three-quarters of an hour. This was when not camping down to stay. I had simply to choose a sheltered place from the wind and sun, make my tent fast under the limb of a tree, and commence operations. All the boxes were fitted with divisions, so that everything could be replaced for resuming the journey in the shortest possible interval.

The supply of water was at times one of my greatest difficulties; for when near the boiling springs I found everything so charged with sulphur and mineral matters that it frequently became necessary to send a distance of two miles or more to obtain a sample sufficiently pure. The natives generally knew where to find it, but it was so thick from being ladled up with a calabash, that I had to allow it to settle before using it; the springs also were often far away from my scene of operations, and fetching the water was sometimes a very vexatious undertaking, much more so than the cooking of food, which in this district was almost an automatic proceeding. During my stay of eight days at Roto Mahana all our food (consisting of hams, fowls, eggs, potatoes, &c.) was cooked either in the boiling holes or by making a hole in the ground in places, when steam would immediately rush forth; by placing our food in a Maori kit or basket over the hole and covering it with fern, it was very soon cooked; in fact, all through the country, up to

the head of Lake Taupo, for over a hundred miles, the natives cook their food in this way. In the foreground of Plate 86 will be seen the hole which served me instead of a kitchen fire, and close by are some native women watching their own cooking operations. On the hill-side, to the right of the picture, was H.R.II. the Duke of Edinburgh's camping-ground when visiting the hot lakes. Plates 79 and 80 will help to explain the active nature of the geysers, from one of which the boiling water rises in a six-foot column to the height of about forty feet, at intervals, which I counted when on the spot as recurring every eleven seconds. I was informed that sometimes it reaches to the height of 100 feet or more. The depth of the principal crater is unfathomed; and I am told that the bottom has never been sounded. All the food for several hundred troops was cooked in this geyser, when they were fighting Ti Kooti in the neighbourhood. It is very dangerous to go too near it. This boiling-geyser system at Tokanu is at the head of lake Taupo, the lake to which I am now referring; it is 1,250 feet above the sea level, and overflows into the Waikato river. At Roto Mahana, or Hot Lake, is a series of chalcedony terraces, of marvellous pink and white colour; the water running over these terraces continually overflows from the crater. At the top the temperature is 212° F.; it fills the different basins, and forms the convenient hot baths in which the natives frequently indulge, and in which they sit in groups for hours together, smoking their pipes. I have bathed in most of these throughout the whole country, and, like the natives, never felt inclined to leave my bath, they are so truly luxurious; the different salts in the water make the skin peculiarly soft; they are a sure cure for rheumatism, but are very relaxing if you stay in too long. Throughout the whole district, from Lake Taupo, going north, to the coast on the banks of the rivers, the temperature can be so modified, by diverting the flow of hot water (by stopping up with a clod of peat), that a bath can be had of any desired temperature. Plates 86 and 94 show some natives enjoying a natural tepid bath. This fact, taken in connection with the magnificent climate of New Zealand, may some day be extensively utilized for curative purposes. At present there is no difficulty in the way, inasmuch as the hostile chief Ti Kooti is no longer a terror, he being safe in his hiding-place in the Waikato country. Good roads have since been formed, and a coach is now running from Auckland through the hot-lake country to Lake Taupo and Napier on the east coast. Military roads are also being opened up all over the country, and redoubts being built at intervals by the armed constabulary for the protection of the settlers and travellers.

## THE PRACTICAL PRINTER IN AMERICA.

### XVI.

#### FANCY PRINTING.

*Fancy Medallion and Arch-top Printing.*—This fancy printing is sometimes very beautiful when the designs for making them are neat and pretty. In selecting designs for this work, be guided by good taste, and do not strive after complicated and glaring designs when the simple and delicate ones are always the object of the tasteful printer.

There are very few designs for this fancy printing more beautiful than that of the fine parallel lines that we are so familiar with in the French writing-paper. Besides the parallel lines, a few others of a delicate design are used very appropriately. Always have the size of the intended prints and the fancy design in harmony with each other; *i. e.*, the larger the size of the print the larger should the design be, and *vice versa*. It would be ridiculous to have large designs intended for an 8 by 10 size photograph used on the common card, as well as it would be to have small designs on large prints.

I have seen a few frame photographs printed in the fancy arch-top and medallion style that I liked very much,

because the design for this fancy work was so very appropriate for the size of the print.

Generally speaking, however, these designs are intended simply for the *carte-de-visite* and the Imperial; sometimes, too, for the Victoria when that style print is made, but they are very seldom used for anything larger.

The making and use of these medallions and arch-tops intended for this style of printing are exactly the same as was described in the preceding chapter, with the exception of the placing of the paper, with the design upon it, upon the print, and then shading the line upon the print by means of the inside mask, as usual. There is also another way, which will be described further on.

The paper suitable for this work is known as the French writing-paper, the thinnest of which should be obtained. A sheet of two or three different kinds will answer very well for a beginning.

Cut the sheets up to the proper size, and after placing your print upon a flat printing-board, put one of these different kinds of designed paper over the whole print, which will be almost entirely covered. Now take the proper mask and proceed to make the crescent line on the print. This is rather difficult at first, owing to the very indistinct print under the white writing-paper, which thus renders the shading of the line rather troublesome. By pressing the white paper in close contact with the print underneath in laying on the mask, and going to a part of your printing-room where you can plainly see your work, you will find that you will have no trouble whatever.

In printing this outside let it darken to the same shade as you would in making plain medallions and arch-top prints; and what I said in regard to plain medallion-printing, about tinting the border to the same shade as the background of the print, is also applicable in this style of printing, the result being equally as bad, with the exception, perhaps, in this case, that there will be a kind of a fancy flatness to the prints, instead of a plain one.

Besides the above, there is also another way to print these, which is, perhaps, easier, because the French paper can be dispensed with, as the glass to which the mask is struck answers the place of the paper. A very thin negative indeed is made of (say) some moss, and developed, fixed, washed, and varnished as is usual in negative making.

The masks are attached to the face of the negative, but it would be better if they were not struck at all, for the negative will, in a short time, be ruined by so doing, and after adjusting the mask the whole is then placed out to print as in ordinary plain medallion-printing. The negative being very thin, the border will darken very rapidly, as quick, if not quicker, than when French paper is used.

*Printing in Gray.*—This term is generally applied to photographs which have been, or are to be, printed first in the vignette style, and then the surrounding white border has been, or is to be, printed or tinted a little. The whole appearance of the mounted print is very often quite pleasing, the darker draperies, &c., of the print being of a rich warm tone, while the slightly tinted border will be of a "gray"-ish tone. When skilfully done, this "printing in gray" is a good thing, and serves to give variety to the printer's results, instead of the monotonous appearance they have in some galleries.

In the first place, in the vignetting of the negatives that are to be printed in this style, do not show too far down in the draperies, although considerable halo may be shown around the head.

The reason why the draperies should not be printed too far down is, because in tinting the border the action of the light on the white sensitive paper *develops the print* in a measure where, in the first place, nothing of the draperies were visible. Bear this in mind.

While the tinting of the border of the vignette print is carried on, the lights of the print would be very much

discoloured if they were not protected from the white light, and consequently a cut-out or mask is made, which answers the purpose admirably. To make this mask, cut a piece of spoiled sensitive paper a *very little* smaller than the figure, as regards the hair, dark draperies, &c., but not a particle smaller in regard to the face. Do not cut too far down in the draperies, or in tinting the print will be spoiled.

The print to be tinted, having been removed from the vignette-board, is then placed in a flat printing-frame, in which a clean glass has been previously placed. Another glass of a larger size is then obtained, to the under surface of which is attached this cut-out, and then, placing the glass so that the cut-out on it will cover the figure in the print, we commence to tint the border of the print, keeping in the meantime the glass constantly on the move. It will take about five to ten seconds to tint all that is required.

In moving the cut-out during tinting of the border, be sure that no part of the face is so exposed to the light as to discolour it.

Always be careful not to tint the border so much as to occasion flatness. A very little tinting is all that is required.

Cotton is generally used by experienced printers in place of cut-outs, but I should not advise the beginner to attempt it until he has had several months' experience in printing.

## THE LIGHT AND THE SUBJECT.

BY R. J. CHUTE.\*

DIFFERENT subjects require a different light. This is well understood by all experienced posers; but there are many who are enquiring whose experience has been limited, and whose minds are open for the reception of such additional light and knowledge as may help them up in the way of improvement towards the goal of excellence. There are certain standard rules or conditions which are to be observed with a subject possessing fair and favourable qualities—that is, regular features, rather fair complexion, and steady nerves. With this class of subjects, we say, light at an angle of forty-five degrees, quite sublel, with about such appearance of light and shade on the face as is desired in the finished picture. From this as a standard there will be encountered a great variety of exceptions. In one direction they run down, through the tender grades of youth, to the soul-harrowing baby that must be caught almost as a bird on the wing; in the other it goes up into the stern and swarthy hues of muscular manhood, and on, through the period of silvering locks and declining years, down to the other end of the scale, where we must deal with trembling, tottering old age.

The fair complexions of children make them favourable subjects for photography, and the difficulty, sometimes, of keeping them still is offset by the advantage of rapid execution. To gain this rapidity, however, usually requires a different arrangement of light, or, in other words, no arrangement at all, for the best method is to use all there is to be had. An impression may be secured in such a light with a very near approach to an instantaneous exposure. With light drapery—which, only, is appropriate for children, and which the photographer should always insist upon—the subject itself becomes a source of light, so that even dark objects surrounding become sufficiently illuminated for very rapid work. From this it will be seen that but little effort or skill is to be exercised in the lighting for very young children, the main thing being to manage them so as to secure an impression with all the light than can be brought to bear. This usually calls for all the resources a man is possessed of.

Proceeding from our standard in the other direction, we soon find exercise for all the talent we may possess in

\* Philadelphia Photographer.

adapting the light to the various subjects that come before us. The first may be one of the lords of creation, who ordinarily might be an excellent subject; but having just returned from his summer vacation, where he has promised his picture to an indefinite number of friends with whom boating, fishing, and hunting, he has become as brown as a piece of bronze statuary, and presents a face almost as difficult to photograph. In country places these subjects are common the year round. To light such a face, the main point is to avoid shadows. The softest light possible must be had, and then the shadows will be strong enough. The resulting picture bears little comparison to the actual light seen on the face; both light and shadows are exaggerated, and violent contrasts intrude themselves, unless great care is taken to get a subdued light, and give a liberal exposure.

The subject with thin features, sunken cheeks and eyes, requires to be set well back from under the light, using a low frontlight as much as possible. A top-light gives the shadows too strong under the brows and on the cheeks, while a side-light makes too much contrast between the two sides of the face, one being strongly illuminated, and the other in deep shadow. Subjects with coarse heavy features, and those wrinkled with age, require similar treatment.

Those with grey or white hair are often excellent subjects, but a diffused light is necessary to avoid rendering the hair an indefinite blotch where the strongest light falls. With many of these subjects something of the Rembrandt style of lighting is very effective. The hair is kept mostly in shadow, and all its detail is given with the utmost fidelity.

As we approach the second childhood of our subjects, the feeble, unsteady nerves often compel a resort to much the same practice that we use in the case of little ones—plenty of light and short exposure.

It is not only the difference in the subject that requires a modification of the light to suit the occasion, but it is the difference in the size of the picture. A light that would be suitable for a small picture, such as a card or cabinet, would not do for one of imperial or half-life size. The larger the picture the less contrast must there be in light and shadow. The theory of this is obvious if we consider that the amount of light received in the middle-tints or half-shadows on the face is concentrated into a very small space in the card photograph (we will say the half of a square inch), and acquires considerable vigour; but when the same amount of light is to be distributed over three or four square inches of surface, as in the half-life size, it becomes too feeble to be sufficiently assisted by any additional length of exposure that may be given. The only remedy, therefore, is additional light in the shadows, or, in other words, but little contrast in light and shade.

#### SECURING GRAIN OR TEXTURE IN PHOTOGRAPHS.

BY HENRY BARRAUD.

ANOTHER attempt to protect methods of securing a stippled texture in photographs, which, being found not new, was abandoned.

"My invention relates to a means of improving the artistic effect of photographic pictures produced by light printing from negatives, and consists in the application thereto of a lined, dotted, stippled, or otherwise varied ground in the manner hereafter described, by which some of the effects of a line or stippled engraving may be imparted to the picture. According to my invention, I obtain upon the sensitized or other surface on which the picture is to be produced an impression from one or more plates, stones, or other suitable printing surfaces upon which lined, dotted, stippled, or otherwise varied designs have been engraved, drawn, or otherwise produced. The character of the ground thus obtained, and the colour of the ink or pigment in which it is printed, may be varied to suit the subject of the picture or of the different parts of the picture to be produced. Instead of applying the said ground to the surface before the photograph is printed, it may be applied after the picture is fixed, either by

printing, as before, from a plate, stone, or other surface, or by transferring (from a sheet of paper or other material upon which the said ground has been printed) an impression thereof to such parts of the picture as may require it."

#### PRINTING WITH OXALATE OF IRON AND GOLD, ETC.

BY W. WILLIS, JUNIOR.

THE following specification describes a series of processes of obtaining sensitive surfaces for printing with oxalate of iron in conjunction with the noble metals, such as gold, platinum, iridium, &c. :—

"This invention has for its object improvements in the chemical treatment of the surfaces of paper, wood, and other suitable materials employed for receiving images from photographic negatives, or from any other object that may be interposed between the light and such prepared paper or other surface. For this purpose, according to my invention, I apply to surfaces of paper, wood, and other suitable materials (by either one or more coatings) solutions or coatings of simple or compound salts of platinum, iridium, or gold, or a mixture of such salts. After this has dried I sometimes apply another coating of a salt or salts of other metals. I then coat the material again using a solution of ferric oxalate, or tartrate, or a combination of these salts with others, and again dry. I then expose the coated surface to light under a photographic negative or other suitable object till a faint brown image appears; after this I apply to the coated surface a solution of the neutral oxalate of potassium or other suitable oxalate, which speedily changes the brown tints to black ones. I then wash the surface thus treated for a short time in a dilute acid, and finally wash in water; but I sometimes immerse the surface in a solution of chloride of sodium, or hyposulphite of sodium, or other suitable salt, before giving it the final wash in water.

"The following are several examples of the operations and manner in which I employ some of the chemicals above referred to in carrying my invention into practice.

"First method.—I coat paper with a solution of chloro-platinite of potassium, containing ten grains of the salt to one ounce of water. After drying the paper, I coat it again with a solution of the nitrate of lead, forty grains of the salt to one ounce of water, and dry it again. I then coat it a third time with a solution composed of ferric oxalate, sixty grains to one ounce of water, with as little oxalic acid as is sufficient to render the fabric oxalate soluble. I then dry the paper and expose it to light under a negative. On removing it from the negative I float it face downwards on a hot solution of potassic oxalate. I then wash it in a weak solution of oxalic acid, then in plain water, and finish by immersing it in a solution of hyposulphite of soda followed by a slight wash in plain water.

"Second method.—In this method I proceed as in the first, but substitute an eight-grain solution of nitrate of silver for the nitrate of lead, and after removing the prints from the weak solution of oxalic acid I finish them by an immersion in either a strong solution of chloride of sodium, or in a weak solution of that salt, followed by a weak solution of ammonia, supplemented in both cases by a slight wash in plain water.

"Third method.—I coat paper with a solution of platinum bromide, twelve grains to one ounce of water, and dry. I then coat it with a strong solution of ferric tartrate, and dry. I next expose this paper to light under a negative, and afterwards float it face downwards on a hot solution of potassic oxalate. I then immerse it in a weak solution of oxalic acid, and finish by washing it in plain water.

"I occasionally vary the preceding operations, or invert their order, or omit one or more of them.

"I would remark that I do not intend to confine myself to the use of aqueous solutions of the chemicals here before referred to, as the salts may be dissolved and used with any suitable solvents.

"I sometimes mix two or more of the salts used for coating the paper or other surface before application.

"Having thus fully described the nature of my improvements, and the manner of carrying the same into practice, what I claim for the production (on suitable surfaces) of photographic pictures in platinum, iridium, and other metals is, the application of solutions of potassic, ammoniac, or other suitable oxalate to such surfaces after they have been exposed to light under a negative or other suitable object, and which surfaces have been coated previous to such insolation with ferric and with other salts, substantially in the manner hereinbefore described."

## TRANSIT OF VENUS.

FURTHER telegraphic reports from other observing parties report further success. Professor Harkniss, in charge of the American expedition at Hobart Town, states that their observations were particularly successful one, and thirteen photographs having been obtained during the passage over the sun's disc. Professor Newcombe, of the Naval Observatory at Washington, remarks that the eighty photographs obtained at Nagasaki and Wladivostock, combined with those taken at Hobart Town, will suffice to give value of solar parallax, with probable error of perhaps 1-40th of a second of arc. Various other successful observations are reported.

The value of the photographs received promises to be very great, and a scientific writer in the *Daily News* remarks that it is possible that photographic observation will quite replace ordinary telescopic observation at the next transit in 1882. The "black drop" and "ligament" apparent in the merely optical observations are reported by Captain Abney to be absent in his photographs produced at Thebes.

The *Times* says:—"With regard to Captain Abney's statement that 'no black drop was apparent in photographs after careful examination,' it is clear that the Astronomer-Royal is of opinion that both black drop and ligament are subjective phenomena, for he remarked that 'photographs were things which had no nerves,' and that, therefore, they put out of the question the possibility of nervous influence. This conclusion we ourselves hinted at when referring to Janssen's observations at Nagasaki. Janssen's Daguerreotypes are regarded by the Astronomer-Royal as beyond comparison superior and more accurate than photographs on glass."

## PHOTOGRAPHY AND CHEMISTRY.

EVERY practical photographer is something of a chemist, although his knowledge of the science is often a very limited one; for it is impossible for any one who has for years constantly practised the art of photography, making up baths, developing solutions, and fixing toning liquids, not to learn something of the nature and reactions of the bodies he handles. For all this, many a modest operator would, we dare say, be as startled at being told he was practising chemistry when testing waste solutions for gold or silver, as Moliere's *bourgeois gentilhomme* when informed he had been speaking prose all his life. Unfortunately,

most photographers do not acquire their chemical knowledge in the best and most straightforward manner, preferring to learn by the practical experience of several years what they might have readily known by a brief study of photographic chemistry. There are those, indeed, who pooh pooh as altogether unnecessary any knowledge of the kind, and boast that they can take bright and clear negatives and brilliant prints without such wisdom, forgetting all the time that, though they themselves may be unaware of the fact, they have come to know intuitively many things of importance, the value of which they estimate but too lightly. They are surprised to learn that what they regard as a matter of course are things of which beginners know nothing whatever, and that they have, in fact, acquired a knowledge—a slight one, no doubt—of the science of chemistry without their knowing it. The definition of science in their minds would be something you don't understand; as soon as you do, it ceases to be a science.

As we have said, to be a good photographer, it is impossible to be altogether ignorant of chemistry, and photographers now-a-days would have far less difficulty with their work if they only knew a little more of the science. There is no reason why every disciple of the camera (no matter how humble) should not be acquainted with the elements of chemistry. His own work has taught him to be careful in his manipulation, and to conduct all his operations with the utmost cleanliness, and these are essential qualities in the performance of all chemical examinations. He may begin very modestly, and need be under no fear of having to read through such bulky volumes as Watt's Dictionary or Gmelin's Chemistry before he can get to work. His aim is not to become a skilful analyst. He only wishes to become acquainted with a few simple reactions; and if he fits up a corner of the bench in his workroom with half a dozen test tubes, a few beakers, a wash-bottle, and a spirit-lamp, he will find that very much may be done with such modest apparatus. A copy of Hardwich's Photographic Chemistry, or some other simple manual, will prove a sufficient textbook; and he can study by degrees, and do a little experimentalizing during his leisure moments.

We are far from supposing even that a photographer would be able under these circumstances to help himself out of every difficulty, but in many of his manipulations a slight knowledge of chemistry would be invaluable. We knew a photographer some time ago who resided near the Essex Marshes, and who was troubled continually with his negatives, the films of which frequently became disintegrated, and left the glass. His practice was to rinse first with distilled water and then with water from a well in his garden, and the defects turned out to be simply due to the large quantity of salt the latter contained; a circumstance he might easily have discovered for himself by adding a drop of nitrate of silver solution to some of the water contained in a test tube. Again, how many correspondents write to us about stains and spots in prints, of the nature of which they are ignorant. Of course, in most instances they turn out to be due to the presence of hyposulphite of soda, and the testing of this by means of iodide of starch is one of the simplest chemical operations, if only undertaken with care and accuracy. The estimation of residues, the testing of photographic requisites for purity, may all be undertaken by a photographer possessing but a slight knowledge of chemistry, and the same may be said of the preparation of many of the compounds that he employs.

But a photographer conversant with chemistry is able to do more than this. He knows the action of the various constituents in his baths and solutions, and the reasons why they work wrong or right. He can turn his waste solutions and residues to the best advantage, and if he cannot dispose of them profitably, can make very good use of them himself. To work successfully and economi-

cally, chemical knowledge is indispensable, just as much as an acquaintance with art is imperative in the taking of good pictures; and we shall hail the day when a course of elementary chemistry will be considered a *sine qua non* for all pupils in photography.

#### PHOTOGRAPHERS AND THE PUBLIC.\*

It is no easy matter to write upon the business relations of the public and the photographer when there is so much difference in photographers, and in the public too. What is good for one is not so for another, and what is in keeping with the public of great cities does not suit that of the provinces. Upon one point only is the public generally the same, and that is in its ignorance of what takes place when it is photographed. Many believe that with the uncapping and capping of the lens everything is finished, and these people cannot for the life of them understand why such high prices should be demanded for such simple work. Others know a little more: they have heard of plates, and have even smelt collodion.

Some time ago I was travelling about, and arrived at an hotel after I had been at work the whole day in a tent in some out-of-the-way district. While taking my supper in the coffee room, I heard several gentlemen near at hand evidently chatting about me, and discussing what I might be (for I should mention, by the way, that I had no outward signs about me, such as blackened fingers and the like). Presently one of them passed close by me who was possessed of a very fine sense of smell, and he snuffed about as he crossed the room, and whispered to the others, "He is a photographer—he smells of Hoffman's drops." The man was quite right; my clothes did smell of Hoffman's drops, or rather of ether, which is common to that patent medicine and collodion.

It would be better, however, if the public knew less about the technical, and more of the artistic, requirements of our art. The man who knows that I use collodion is of little assistance to me when I take his portrait; but he who is aware that to produce a happy portrait a tasteful arrangement of the dress is necessary would have no objection to place himself in the hands of the photographer, and would not talk of matters which are simply impossible. I remember the case of a young lady who was just engaged, and who desired to possess a picture of herself dressed in the garment in which she had first appeared before her intended husband, with her hair arranged in a certain fashion, and dressed with some white flowers at the back, which she desired should be visible.

"I can only take you in profile under those circumstances," I said.

"Oh, pray don't do that," was her reply; "I never take well in a profile position. I must have a full face portrait."

I explained that the flowers in her hair would not then be visible, and suggested as a compromise that they should be placed more to the front. But to this she would not consent, and prepared to take her leave forthwith; so I suggested to her that the only way of overcoming the difficulty would be to have a bust of herself wrought in marble.

Some time afterwards I had to do with an amiable lady, who was something of a blue-stocking, and who was very proud of her somewhat sparse, though genuine, locks. This lady, also, wanted a full face portrait, and yet was exceedingly anxious to show her back hair. I helped myself out of the difficulty by employing a mirror set up in the rear, which gave a picture of the hair behind. It was a little unsharp in the negative, but that did not much matter; I retouched a little, and put in a few extra locks. The result was highly approved, and paid for, although, I must admit, the head-dress did not look very natural, after all.

The dodge with the mirror is not, of course, a new one. Those who make use of it will, however, find that it is by no means an easy matter to obtain the model and the reflection in the looking glass, both sharp, at the same time. It is an error to suppose that the mirrored image lies upon the surface of the mirror. I know a secret-process-maker who sells, among other things, a method of photographing an interior with a portrait, without a diaphragm, and yet producing everything very sharply; and his instructions are to photograph everything reflected in a looking-glass. Those who try the experiment will find that, in focussing, the reflected image is quite as difficult to render sharply as the direct image. "The picture lies just as far behind the mirror as the object is before it," says Professor Pisko in his work upon Light and Colour, a book from which photographers may learn a great deal. The nearer, therefore, the mirror is approached to the model, the easier will be the operation of focussing.

I may here remark that the taking of portraits in the presence of a looking-glass is a task in which the most practised photographers do not always succeed: there is to be seen in the shop windows the picture of a princess—a three-quarter portrait, with a mirror. You can see from the picture that the photographer has essayed to show the royal model in profile in the looking-glass, while she herself is depicted full face. The mirrored image was not, however, successful, and to cover the defect it has been tinted in the sunlight. Fortunately the public is unaware of the failure, for it generally sees mistakes enough where the photographer is unaware of their existence, and often refuses pictures which really are very fair productions.

Frequently the public, in pronouncing against a picture, will not specify the particular point they find fault with—when, for instance, it is one for which they themselves are alone responsible. Thus a lady who is in the habit of biting her lips will have nothing to do with a picture in which this is shown; she does not, however, tell you her reason for disliking the picture, for she knows very well that the fault has happened from no fault of the photographer; and it is not often, therefore, that the latter gets to know the real cause of dislike, for the model advances other reasons for her rejection of the picture.

The best way of overcoming such difficulties as these with the public is to make prepayment obligatory. I travel about a good deal, and as I like to look at the different studios I come across, I get my portrait taken *incognito* by my colleagues, paying, of course, for the service, and hearing and seeing what I can. I never grudge the money, for I always learn a good deal; and I have found lately that the custom of prepayment is becoming every year more general. Half the amount of the fee is taken in advance. Whether this rule works as well in the provinces as in the capital I must, of course, leave to my colleagues to decide. A great point is the proper management of one's customers, and some conversational powers and worldly experience are necessary for the purpose. The photographer who has these qualities will be able to control the sitter and have his own way much more than a shy, nervous, and inexperienced operator, who becomes exceedingly embarrassed when he has to do with a person of high rank or noble position. As I am not only a photographer, but have frequently been a model myself in many studios, I have been able to acquire many interesting experiences on this head. While one photographer will allow the model to sit down as he likes, will make but few remarks, and very slight modification in the pose, and in a few seconds has done his work, another pulls and tugs at every corner and fold in one's garments, pushes your head this way and that, now full face, now profile, takes a quarter of an hour to arrange you, and, at the last moment, takes quite another view of things, exposes a plate, and then begs for a second sitting, as the first has not been quite successful.

I could talk a good deal about this matter concerning

\* Photographische Notizen.

the public and the photographer, but I won't tell tales out of school. Some very good hints may be gathered from Hartmann's little book on the subject;\* it only contains sixteen pages, and it is interesting to read, and will spare the photographer many explanations. It is distributed gratuitously in many studios.

In conclusion, I may refer to an anecdote that comes to us from America, and which is no doubt known to many already. "What do you charge for a picture?" said a labourer one day to a photographer. "Two dollars," replied the latter. "Very good, then, let me have a half length portrait, and I will pay you one." The photographer closed with the bargain, received the dollar, and in a few days sent the labourer his half portrait, but it was the lower half from his coat-tails downwards. The labourer of course pulled a long face over the business, and asked for the other half. But this was not, of course, handed over until another dollar had been paid.

### AMERICAN CORRESPONDENCE.

#### THE SEASON OF YEAR-BOOKS—MR. SHERMAN'S THREE-YEAR-OLD BATH.

*The Season of Year-Books* is at hand, and *Photographic Mosaics* has so occupied my spare time recently that I almost became guilty of forgetting my obligations to your readers in the matter of correspondence. I will, however, try to make up for it by giving you in advance some of the choicest things in the *Mosaics* for 1875.

*Mr. H. Sherman's Three-Year-Old Bath.*—Mr. H. Sherman, one of our most able teachers, ridicules the idea of constantly making up new baths, and sends me the following remarks on one he says has been in constant use for over three years. He says of it:—

"The first week in September, 1871, after a series of experiments, I prepared the bath which I am now using, and which has been in constant use ever since. It has never been boiled, nor have any means been employed to rid it of ether or alcohol, and there has never been a drop of alcohol added to the developer used in connection with it. It was sunned at first to precipitate any substance susceptible to the action of light, since which, exposure to sunlight has failed to produce hardly a perceptible effect upon the solution, usually not causing discoloration. It originally measured six gallons, at about which quantity it has been maintained most of the time by such additions, as required, of solution composed and prepared precisely as the original bath, except that no salt of iodine has been added with the subsequently prepared portions. It works to-day (September 26th, 1874) in every respect as well as it did three years ago; as well, at least, and, if my recollection is not at fault, decidedly better.

"Without enlarging further upon the merits or peculiarities of this bath, I will say that the experiment seems to be an important one, indicating, as it does, the possibility that a bath may be so constituted as to maintain, through the variable conditions consequent upon continuous use, the qualities or structure, so to speak, adapting it to the discharge of its required functions.

"Suppose a bath so constituted as never to need any treatment, save only replenishing and the removal of sedimentary matter or filtration. This is as near perfection as is ever possible for a bath. Even the life of an organism requires as much. Whether the bath under consideration shall fully answer such description or not, is not the experiment, if correctly reported, worth repeating? Assuming the affirmative, I will proceed to describe the method of preparing the solution.

"Take ice-water, sufficient quantity. In each quart (32 fluid ounces) dissolve 3 ounces of nitrate of silver. For each ounce of silver nitrate, add 1 grain each, previously dissolved, iodide and cyanide of potassium. Let the solution stand a few hours, shaking occasionally; after which filter. Then, to each quart of the liquid add one-half fluid drachm glacial acetic acid. Next add slowly, and with constant agitation, sufficient saturated solution of bicarbonate of soda to neutralize the acid. Set in the sunlight until discoloration ceases. Again filter, and finally make slightly acid, by adding a few drops of pure nitric acid.

"A peculiar reaction takes place, on the addition of the acetic

acid, which it is not necessary to consider here. The excess of this acid being afterwards neutralized by the sodium salt, it follows that acetate of soda is formed in the bath, and that, on addition of the nitric acid, acetic acid is substituted therefor, so that virtually no free nitric acid remains present.

"One peculiarity of this bath is, that the usual annoyances arising from the accumulation of ether and alcohol are, in some way, dispensed with; the ether and alcohol being converted into other products, in the main not impairing, if not positively aiding, the acting forces of the bath.

"Another peculiarity is, that the presence of a considerable quantity of acetate of soda does not result in the formation of acetate of silver. Immunity from this anticipated trouble is probably due to the cyanide.

"When the pinholes which denote over-iodization begin to appear—and this by no means happens prematurely—the bath is replenished by adding sufficient uniodized solution (prepared as at first, omitting only the iodide) to make up for loss of bulk and strength. Filtering occasionally becomes necessary from causes such as usually lead to this operation.

"The bath becomes more strongly acid by use, acetic acid being one of the products into which the ether and alcohol are converted. When from this cause its sensitiveness becomes sensibly affected, which is an unfrequent result, I correct the over-acidity by again adding bicarbonate of soda, thus partially neutralizing the acid, and adding a fresh supply of the sodium acetate. The number of times this treatment has been required during its lifetime has not been such as to cause the appearance of the unwelcome silver acetate.

"I have used this bath under a great variety of conditions, in and out of the studio, in strong and weak light, in summer and winter, with all manner of subjects, such as family groups, on large plates 14 by 18 to 17 by 20, consisting of white-robed children and black-draped seniors; subjects requiring long exposure, such as badly-lighted interiors and subjects intensely lighted. It gives a high degree of sensitiveness, together with detail and density. Infants are taken in the shortest possible time. The details of white drapery are exceptionally well rendered; the tendency to hardness or solarisation is seldom exhibited. Such certainty of satisfactory results, and such uniformity of action, I never before experienced and enjoyed.

"Whether, like 'the deacon's one-horse shay,' it will run exactly one hundred years to the minute, and then, all at once, turn into a small heap of dust, is what I want to know.

"It is recommended to the craft as an improvement worth trying. Let those who are so disposed give it a careful trial, following the directions above given for preparing it, without variation, at first; and, if found to be a good thing, let those who so find recommend it to others."

(To be continued.)

### A SUGGESTION.

BY WM. BROOKS.\*

You may think it a strange suggestion I have to make this evening. If it is carried out, I think it will be the means of creating a greater interest in the meetings of photographic societies, and may, perhaps, be the means of having them better attended, and, at the same time, will be a connecting link between the photographic societies throughout the world wherever photography has established itself; and I think the South London Society a very suitable one to introduce the matter to the notice of other societies, both at home and abroad.

It is this: to establish an exchange of photographic portraits (carte size, I think, will be most suitable) between the various photographic societies—in the first place, of all the office bearers of the societies and of other notabilities who have rendered such valuable aid to the advancement of our "art science;" such gentlemen I may mention as Mr. Carey Lea, the Revs. Canon Beachey and F. Hardwick, Mr. Thomas Sutton, and many others, not forgetting our worthy Editors. I am sure none would object to contribute to an album of a society provided and kept for that purpose, to be placed on the table each meeting night for the inspection of members. I think myself that if such a

\* A translation of this has appeared in our columns.—Ed. P. N.

\* Read before the South London Photographic Society.

system were adopted it would create a very great interest indeed to both amateur and professional photographers, and it would give greater interest to articles written when all of us would be able to see the portraits of the authors at our societies. There are scores of gentlemen of whom we have only heard by reading, and if we cannot see them to know them personally, it will, I think, be a step in advance to see their faces in the way I have stated. I am sure no society would object to further such an object. It also would enable many of us to recognize gentlemen who attend our annual technical meeting whose acquaintance many of us would like to make, and only know of their presence by seeing their names on the visitor's book.

I should be most happy to render any service in putting this suggestion in force. Should it meet your approbation, the new year, I think, would be a very suitable period for its introduction.

### HOW TO PRESERVE ALBUMEN.

BY GUSTAVE RE.\*

IF white of egg, after it has been beaten to a froth, and allowed to stand, is mixed with a little hydrate of chloral, in the proportion of five grammes of the latter to one hundred of albumen, the mixture may be kept in closed vessels for a considerable time without emitting any evil smell, or altering in any way in its qualities. If paper is coated with the albumen thus treated, to which chloride of ammonium, or common salt, has been added, as is the case when albumenized paper is prepared, there is no difference to be remarked between such albumenized paper and the material purchased in commerce. But I have remarked that an albumenized surface containing chloral keeps white for a longer period than one produced by means of half decomposed albumen.

The hydrate of chloral is without action upon a neutral or acid silver solution. The quantity that it is necessary to add to the albumen is very little; the greater part of this, too, evaporates on the drying of the paper, so that no injurious action upon the silver bath is to be feared.

To albumenized paper manufacturers this substance ought to be very useful, for not only does it render the work-rooms free from bad-smelling gases, but it permits the manufacture of a material which does not carry with it into the photographer's studio an objectionable odour.

The ordinary pyrogallie acid developer, which can be preserved for but a short time under ordinary circumstances, may also be treated with hydrate of chloral with similarly good results. It will then keep good for a longer period, with none of its previous qualities impaired. In many other ways hydrate of chloral may be made use of as a preserving medium; it is only necessary to prevent its coming into contact with strong alkaline liquids, as hydrate of chloral is soon decomposed into formic acid and chloroform.

### Correspondence.

#### KENNETT'S GELATINE PELLICLE.

SIR,—If Mr. Kennett's specification includes nothing beyond what had been previously published, which from the letter of "A Worker" seems to be very probable, I think he is deserving of both thanks and sympathy. Thanks, for having wrought out the gelatine emulsion process so thoroughly, and for placing it in so convenient a form before the public on terms so liberal that it seems doubtful whether it can possibly remunerate him; and sympathy for having made so expensive a mistake in obtaining a patent. I say mistake, for no one can believe for a moment that he knew

that the details of his supposed discovery had already been published, for the veriest child in such matters knows that prior publication invalidates a patent. Hence it is manifest that he believed his discovery to be new. Had he known that it was not he would probably have saved himself much trouble, and probably also photographers would have been deprived of the advantage of his pellicle, for without believing it to be his own, and duly protected, it is scarcely likely he or anybody else would have entered upon the enterprise of its manufacture. If "A Worker's" statement be accurate, no one but Mr. Kennett is any the worse, and photographers are the better for the possession of his pellicle which may yet prove a great boon.

I have said "if" "A Worker's" statement be quite accurate; but I suspect that, although it may be the truth, it is probably not *all* the truth. When Mr. Kennett read his paper before the Photographic Society, he stated that he had experimented with gelatine for many years. I suppose such a statement is capable of proof, and this would show that he was not indebted to the comparatively recent publication of others for his knowledge of gelatine emulsion. Photographers are indebted to "A Worker" for his exertions in their interest; but a word on the other side is, I think, due.—Yours,

ANOTHER WORKER.

SIR,—I have no wish to fill your columns with discussions upon the value or worthlessness of Mr. Kennett's patent—that I deem a point for his consideration alone. My desire rather is, in the interest of my fellow-labourers, to state, for general information, my experience regarding Mr. Kennett's pellicle, which, in rapidity, cannot be approached by any of the commercial plates now extant. It is very much cheaper, and will, no doubt, eventually supersede those now patronized by the profession.

"A Worker," avoiding any consideration of the pellicle, dexterously bases his attack upon the patent. Possibly those amongst us who are of a speculative turn of mind, and might have been tempted to make Mr. Kennett a bid for his patent, ought to feel grateful for "A Worker's" interference; whilst others, like myself, who aim only at obtaining the latest improvements, will merely look upon his zeal as calculated to deprive us of an invaluable boon. I also fail to follow "A Worker's" argument that Mr. Kennett's action has barred the public from the use of a certain discovery bequeathed it by Messrs. Johnston and Maddox. If their pellicle is really easy of manufacture, and trustworthy in its results, why is it so little known? Where can negatives and proofs be seen? In how many studios has it found favour? I crave enlightenment.

As an amateur photographer, I feel indebted to Mr. Kennett for his pellicle, which, I hope, I may always find as excellent as I now believe it to be; but should he or anyone else discover something more rapid and equally reliable, I should not ride conservatism to death by sticking to my old love.

In conclusion, I must state that I hold that a correspondent should be man enough to avow his name when making innuendoes, rather than take shelter in a "nom de plume."  
—Yours faithfully,  
S. S. YOUNG.

Fairmile, Cobham, Surrey, Dec. 14th.

SIR,—As Mr. Aldridge, in a letter in your last, states that Mr. Kennett "exhibited negatives and prints at the Technical Exhibition of November, 1873," it is necessary for me to call the attention of your readers to the exact date of that Technical Exhibition. It was November 27, 1873.

Now, as I have shown in your last that the making of a gelatine emulsion, and the method of allowing it to become solid when it was to be cut in slices, and then washed to remove the excess of bromide, had been published at the dates of September 8, 1871, August 8, 1873, and November 14, 1873, and that Mr. Kennett actually patented these very

\* Photographisches Archiv.

things on November 20, 1873, following very closely even the words of the gentleman who had previously published the whole process *pro bono publico*, it is necessary that no misconception should occur, and that it should be plain that Mr. Kennett's "discovery" was in no way original.

A WORKER.

SIR,—In Mr. Aldridge's letter in last week's NEWS he is pleased to say that my communication of the 4th contains "much personal abuse" of himself. I am quite sure that if this statement contained one iota of fact you would not have allowed it to appear. I could have no object in abusing Mr. A., who is totally unknown to me.

As an amateur, I was merely seeking information in regard to a process with which I have only partially succeeded, but which I have always felt had good and promising qualities. I hope that Mr. A. will, upon a re-perusal of my letter, see that he has been rather hasty in stating that I have been guilty of so ungentlemanly an act as to abuse him or anyone else.—I am, sir, your obedient servant,

A DRY PLATE.

SIR.—In answer to "Dry Plate's" request I will endeavour to give my experience. First packet worked according to the formula: the plates took ten minutes to develop a faint shadow; trying to get them dense, the film burst up. Cause: the ammonia and bromide not fresh. Second trial: pictures came out on applying fresh chemicals, with bromide in excess of formula; they came out in ten or twelve seconds, but still burst up on applying intensifier. Cause: insufficient washing between developing and intensifying, the ammonia and acid making a kind of effervescing mixture. Third trial: succeeded in getting a transparency by contact printing, but still not able to get sufficient intensity without discolouring the film, slightly fogging, when we were compelled to stop. I called on Mr. Kennett, who showed me some excellent negatives, and developed a transparency on one of the plates I had prepared. He told me I had not got enough pellicle on the plate. Bought some more, and went home to try again. The difficulty we find is to prepare—or, rather, to dry—the plates, as they have to be done with so small an amount of light.

I also tried to take a few negatives, but found much the same difficulty. I certainly got a negative that printed, though not a work of art by any means. I think much of my failure was owing to the light I worked in being too strong. Mr. Kennett's light is two thicknesses of orange-coloured glass, and he has two doors to the dark room, so as to more effectually exclude light. He gave me a great deal of time and attention, and I think when anyone has succeeded in working the process it is invaluable. I have not had time for still further trial, and may say, in conclusion, that I have had no experience in dry plate work of any kind before, always working the ordinary wet process, which I think is less rapid than the pellicle. I enclose a transparency for you to see.

W. J. DAVIES.

29, Church Street, Stoke Newington.

[The results forwarded have many very fine qualities.—Ed.]

SIR,—It is not greatly to the credit of photography that there is to be found in its ranks individuals who, like "A Worker," retire behind the hedge of an alias, and from that safe retreat can attack my patent with missiles he would hesitate to employ in the more honourable arena of personal combat. I have pleasure, however, in saying that he has overreached himself, for his attack upon myself and my patent has only had the effect of making more widely known my pellicle, and, incidentally, the plates prepared by it, on the manufacture of which I am to be engaged.

The citation of the names of Dr. Maddox and Mr. Johnson, and the innuendo indulged in by the "Worker" that I obtained from a letter published on the 14th of November,

1873, all the information that was embodied in my patent, is a *suppressio veri* easily met by giving the following extract from an article by the editor of the *British Journal*; and I invite attention to the fact that the article was published on the 15th August, 1873. I imagine it will require all the casuistry of "A Worker" to prove that August 15th is later than November 14th.

The article is headed "Substitute for Collodion," and the writer goes on to say: "Among those who are actively engaged in experimenting, with a view to providing a substitute for collodion in the bromide emulsion process, is a well-known amateur, Mr. Kennett, of Maddox Street. This gentleman has within this last fortnight 'resumed' some experiments with gelatine which he began several years ago, but discontinued from not having obtained such vigour as he required. Since the subject has been brought so prominently forward, as it has of late, Mr. Kennett has repeated his experiments with a considerable increase in the amount of bromides. The result has been singularly successful. We have now before us two negatives with a film of such smoothness and hardness as might easily be mistaken for albumen, and altogether we are pleased to be able to say that in our next we shall publish working directions, which have been kindly promised by Mr. Kennett. This gentleman appears to have overcome a difficulty encountered by several, viz., making the emulsion to keep."

It may suit "A Worker" to speak about my name never having been known in photography previous to my applying for a patent. The quotation given above disproves the suggestion. It is true that I have not courted that publicity so sought for by some, who continually obtrude their names before the public, no matter on how flimsy a pretext; still, my name was not quite unknown even before that time; but even if it had been, what then?

This is not the place for me to enter into a defence of my patent, and to show that "A Worker" has abstained from touching the real point of my invention. I am ready, however, to give every information that may be required, but must decline to do so at the instigation of anonymous writers, who vilify a process that I venture to predict will, ere long, drive out of the market all the much vaunted and so-called rapid dry collodion plates, the most rapid of which are, by comparison, exceedingly slow.

R. KENNETT.

[This discussion has already occupied too much space, and must cease for the present. The pellicle, which already promises well, will be best tested by practical trial, and the validity of the patent can only be efficiently discussed in a court of law.—Ed.]

#### PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

DEAR SIR,—Will you kindly grant me space to announce that the First Annual General Meeting of the Photographers' Benevolent Association will be held at the Co-operative Institute, 55, Castle Street, Oxford Street, on Monday, January 11. After the despatch of business there will be a Siopticon Exhibition, exhibition of the prizes in the Art-Union distribution, and a musical entertainment by photographic friends. There will be microscopes, graphoscopes, and other scientific apparatus. Refreshments will be provided at a reasonable price, and special arrangements have been made to secure the comfort of ladies.

Further particulars will be announced as to programme in due course.—I remain, yours respectfully,

174, Fleet Street.

W. T. WILKINSON.

P.S.—I shall be glad to hear from any one who has objects of interest for exhibition on this occasion.

### Proceedings of Societies.

#### PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Ordinary Monthly Meeting of the Board of Management was held at 174, Fleet Street, on Wednesday, December 2nd, W. S.

BIRD, Esq., in the chair. Minutes of previous meeting having been read and confirmed, Messrs. Croft, Berjemant, and Laing were admitted members of the Association.

The Secretary was instructed to engage a hall for the Annual General Meeting, on Monday, January 11th, 1875, for which occasion the Secretary announced that W. B. Woodbury, Esq., had promised to lend a sciopticon and slides. B. A. Ferneley, Esq., F. York, Esq., and R. Kennett, Esq., had also promised slides.

The Secretary laid before the Board a request from the Art Union Sub-committee for a grant of money for the purpose of advertising and carrying out the Art Union Distribution.

The Chairman having expressed his opinion that such a course could not be taken without a guarantee that the funds would not suffer in case of failure, a guarantee fund was subscribed by the members present. The sum of £10 was then voted for the use of the Art Union Sub-committee. After the transaction of routine business, the meeting was adjourned. W. T. WILKINSON.

#### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE annual meeting of this Society was held in the rooms of the Society of Arts, on the evening of Thursday, December 10th, Mr. T. SEBASTIAN DAVIS in the chair. The minutes of a previous meeting having been read and confirmed, the following gentlemen were elected members of the Society:—Messrs. Wratten, Skinner, S. Fry, and W. H. Wainwright.

After some conversation on various points of business, the Secretary read the following

##### Report of the South London Photographic Society for 1874.

"Your committee, in presenting their report for the session of 1874, most heartily congratulate your Society upon the healthy vitality and consequent strength which have characterised its existence during the past year. In addition to a very large increase of members, whom it is confidently anticipated will render valuable assistance to its proceedings, the past session has brought the South London Photographic Society prominently before the photographic world, in maintaining itself as the medium of what is new, instructive, and thoughtful.

"The institution of a Technical Exhibition, which your Society inaugurated, has this session been brought under the control of regulations which has placed it upon a firm basis, and which, in future, will make this meeting exceedingly useful and attractive. The ordinary meetings have been attended by a very large percentage of members, and great interest and animated discussions have shown the value of the subject matter brought before the Society.

"Your Committee have to acknowledge their indebtedness to the Society of Arts for so kindly placing one of their rooms at the disposal of your Society for its ordinary meetings.

"The following papers have been read during the session, viz.:—'On the best way to make Enlargements,' by B. J. Edwards; 'My Troubles in taking Direct Large Heads,' by W. Aldridge; 'My Experience in taking Direct Large Heads,' by H. Garrett Cocking; 'On Studios,' by S. Fry; 'On various Colouring Matters suitable for Tinting Films,' by J. Spiller; 'On an Apparatus for Reducing Silver Wastes,' by J. Bashford; 'On a Method of producing Large Composition Groups,' by B. J. Edwards; 'Suggestions for a National Congress of Photographers,' by Jabez Hughes; 'Principles and Practice of the Portrait Painters,' by A. R. Aldridge; 'A Suggestion,' by W. Brooks.

"One meeting was devoted to a conversation upon the subject of the permanency of prints, introduced by the Secretary and another to a practical demonstration, by Mr. Wratten, of the production of negatives by the Obernetter process.

"Photographs, apparatus, and appliances, have been exhibited by the following gentlemen, viz.:—Messrs. B. J. Edwards, S. Fry, H. Garrett Cocking, J. Spiller, Kennett, F. Howard, Wilkinson, Tully, Bashford, Oakley and Co., W. Hueter, Spencer, Sawyer, Bird and Co., Harrison, Cussons, Miers, Attwood, and the Secretary.

"A considerable amount of work has thus been got through during the session; and, in conclusion, your committee trust that the same principles of social, pleasant, and happy intercourse which have hitherto guided your Society in its deliberations will always be maintained, and thus tend to promote, not only the pleasure and interest of each individual member, but also the further study and general progress of our art-science."

The Treasurer's report was then read, and showed a balance in hand of £18 5s. 1d.

The election of officers for the ensuing year followed, Mr. Davis previously stating that having held the office of vice-president for fifteen years, ever since the foundation of the Society, he felt it now desirable to resign, because other duties would claim his attention, and he thought change now and then in the officers was desirable. The following officers were elected:—

*President*—The Rev. F. F. Statham, M.A., F.G.S.

*Vice-Presidents*—G. Wharton Simpson, M.A., F.S.A.; Valentine Blanchard; Jabez Hughes; J. Spiller, F.C.S.; and F. York.

*Committee*—Messrs. Bridge, Brooks, Hueter, Foxlee, Morgan, Aldridge, Wilkinson, and Ayres.

*Treasurer*—Noel E. Fitch.

*Hon. Secretary*—Edwin Cocking.

Votes of thanks to Mr. Davis, Mr. Fitch, and Mr. Cocking having been passed and acknowledged,

Mr. ALDRIDGE read a paper on the "Principles and Practice of the Great Portrait Painters." A number of photographs by M. Adam Salomon, Mr. Blauchard, Mr. Crawshaw, and others were exhibited in illustration of certain points. Owing to the lateness of the hour the discussion was postponed; we shall therefore postpone the publication of the paper for a few weeks.

Mr. BROOKS read a brief paper suggesting a system of exchange of papers between societies (see p. 608).

After some conversation the proceedings terminated.

### Talk in the Studio.

KEEPING QUALITIES OF COFFEE PLATES.—A correspondent, Mr. J. Turnley, informs us that he has just secured two good negatives on coffee plates prepared by himself in March, 1872, or two years and three-quarters ago. They received eight times the exposure required by a wet plate, developed easily and quickly, and are without fault.

FILTER FOR NITRATE BATH.—A correspondent of the *English Mechanic*, referring to the filter described by Mr. Speight some time ago in our columns, says:—"If the bath has been poured into a wide-necked glass bottle, in which a stop-cock is fitted at about  $\frac{3}{4}$  in. from the bottom, and allowed to settle, it can be drawn off by the cock perfectly bright and clear, without the least trouble or inconvenience."

IMPERIAL PORTRAITS.—A writer in the *Daily News*, in speaking of the influences used to secure a Bonapartist reaction in France, says:—"Some three million photographs of the Emperor or Prince Imperial, with seditious mottoes (we quote official figures), have been seized by the police. But how many have escaped unseized? M. Haentjens, member for the Sarthe, who manages the photograph department of the propaganda, could alone tell how many portraits have been issued."

AUBELTYPE is said to be a new process invented by Aubel and Kaiser, of 38, Lindenhöhe, Cologne, for the purpose of rendering photography serviceable in lithography.

BLACKENING SHEET ZINC.—The following is a new process lately discovered for obtaining zinc sheets of a solid black colour. The sheet of zinc is cleansed by hydrochloric acid and sand, and then plunged into a solution of equal parts of chlorate of potash and sulphuric acid. A slight velvety-black deposit is immediately formed. The plate is carefully washed with water, allowed to dry, and then plunged into a solution of asphaltine in benzine, left to drain, and rubbed with a piece of cotton rag.—*American Chemist*.

### To Correspondents.

\*\* TO AGENTS AND ADVERTISERS.—Next Friday being Christmas Day, the PHOTOGRAPHIC NEWS will be published on Thursday, December 24th. Advertisers should send in their Announcements not later than Wednesday, the 23rd.

J. A. DUNCAN.—It appears to be an imprudent course to continue to advertise one scale of price, and in practice adopt another, but you will see it is a matter in which we cannot interfere in any way, as we have no responsibility or connection whatever with the announcements of advertisers. As we understand the matter, you were informed of the revised scale before the work was done, and the simplest plan would have been to request the return of the money and the negatives, if you were unwilling to pay the higher rate.

**ENCAUSTIC.**—The use of encaustic paste for finishing photographs we consider to be on the whole beneficial, and we have never seen any that became yellow or injured in any way by the use of encaustic. We have some prints by M. Adam Salomon, produced about eight years ago, and treated with his encaustic paste (the formula of which we published) in which we see no change whatever. If turpentine be used in making the paste there may be a tendency to become yellow. The copies of Vogel's Handbook are promised, but have not yet arrived.

**ALBERTYPE.**—The Woodburytype and Albertype are both photo-mechanical processes, and are best suited to the production of large numbers. The term Autotype as now employed is not, when used alone, sufficiently distinctive, as it is applied to a photo-mechanical process analogous to Albertype and to carbon printing. The latter is better suited to the production of small quantities than any of the mechanical processes, because, in both the photographic processes and the Woodbury process, the first preparation of the printing surface requires time and care, which would scarcely be repaid by the production of a small number of prints. The Albertype process is not patented in this country. The Woodburytype patent has expired. The carbon process is patented, but there is comparatively little restriction placed by the patentees on its use. The Autotype Company issue a manual with full instructions. There is no work devoted to either of the other processes.

**MELBOURNE.**—There are various methods of producing photographs on ivory which we have published. The simplest consists in coating the ivory with collodio-chloride of silver, and printing, toning, and fixing in the usual way; but there is always some risk of the print changing from not getting rid of the hypo used in fixing. We prefer to print deep, therefore, and fix with cyanide. But it is, perhaps, safer to transfer a print produced either by collodion printing in the camera, or by collodio-chloride, or by the carbon process. The latter is now most generally used for ivory. We have more than once described the details, and you will find them in the Autotype Manual issued by the Company.

**CARBON AMATEUR.**—The powder process has been used and patented for carbon printing. Mr. Window obtained a patent some years ago, the details of which closely resemble those now used in reproducing negatives. Here is his formula:—

Honey ... ..	2 parts
Glucose ... ..	4 "
Albumen... ..	3 "
Dextrine... ..	1½ "
Saturated solution of bichromate of ammonia	7 "

Spread this sensitive solution upon paper, ivory, canvas, wood, &c., then dry it by means of heat, and expose it under a transparent positive to light. When exposed sufficiently, brush powdered pigment over the surface until the image is sufficiently developed, and proceed to fix the pigment on the surface of the paper or other material. Effect this by laying the print, immediately after being developed, in a flat dish, and pouring alcohol, naphtha, or some other such agent over it, wetting both back and front; the print is then hung up to dry spontaneously, or a gentle heat may be employed. When quite dry, it is immersed in a dish of water acidulated with hydrochloric, sulphuric, or some other acid, which will dissolve out all the soluble portion of the coating. The print is then soaked for a short time in clean water, and finally passed through a dish of water rendered slightly alkaline with ammonia, to expel any trace of acid.

**W. M.**—A single lens is not well suited for architectural work, as it will inevitably give some degree of curvature to straight lines. One of the doublets or a rectilinear will answer your purpose best, as it serves well for either landscape or architecture. We cannot very well recommend special lenses in these columns; but if you send a list of any you contemplate, with distinguishing names or figures, we can better help you.

**CRANKY.**—To produce a transparency by contact printing, you must use a dry plate prepared by any of the dry plate processes you may determine. The exposure will not need to be more than a few seconds to daylight, or about one minute to a gas flame. The coffee process, or the morphia process, or some of the more simple processes, will answer; but whichever you select you must follow the instructions carefully. A simply washed collodion plate such as you describe will in some cases yield a good picture, but something depends on the quality of the collodion; but an exposure of fifteen minutes to sunlight, and fifteen minutes more to daylight, under a negative would, in all probability, give you nothing but a fogged plate. But suppose the exposure to have been right, treating it with an iron solution without any silver present would not yield an image, but would rather tend to destroy any image there was. Iron developers or pyro developers with acid require a few drops of silver added before an image is produced on such plates. You may produce transparencies on wet plates if you place strips of thin card at the corners to prevent absolute contact, but of course there will be a little loss of sharpness. You will find several dry processes in our forthcoming YEAR-BOOK. It is desirable that a muffle should be heated all round to secure uniform heat.

**F. J. D.**—We fear that you will need to practice a little more before you can obtain an operator's situation. Merely practising open air portraiture, will not readily familiarize you for all the varying conditions with which you must be well acquainted in studio work, of which producing varied effects in lighting is an important feature. No. 1 is not quite sharp, and lacks the relief produced by proper contrast of light and shade. No. 2 is under-exposed. Get a few good portraits, and try to produce results quite equal to them.

**C. HORNE.**—Excess of acid in the nitrate bath will, under ordinary conditions, actually render the plate less sensitive; it will also retard development. There are conditions in which excess of nitric acid seems to give increased sensitiveness; but they are not well defined. Ordinarily, excess of nitric acid is believed to have a tendency to destroy the latent image as it is formed, and thus actually retards its production. 2. The greater the proportion of acid in the bath, the less the proportion necessary in the developer. 3. The chief offices under Government in which photography is necessary are filled by military photographers. There is a photographic staff at Chatham in the Engineers, and another at Woolwich in the Artillery. So far as we know, these would generally furnish photographers for all Government work. The interior and the combination print are both good.

**T. H.**—To produce transparencies in carbon you simply make sensitive carbon tissue, expose, immerse in water, attach to a sheet of glass in the usual manner, and then develop. The result is a carbon transparency.

**R. B.**—An iron crucible does not answer well. The best are of clay, and are known, we believe, as London pots. 2. The engravings in question are generally copyright, and can only be reproduced by permission. 3. French pyrogallic acid will serve.

**JOHNSON, MATHEY, AND Co.**—Thanks. We shall have pleasure in using the information.

**MAULL AND Co.**—The markings have the appearance of mechanical injury, as though the prints had been roughly used at some stage of their progress. Drying before a fire will sometimes produce such cracks.

Several Correspondents in our next.

**METEOROLOGICAL REPORT FOR NOVEMBER.**

BY WILLIAM HENRY WATSON.

Observations taken at Braystones, 36 feet above sea level.

Date.	THERMOMETER.			BAROMETER.			Direction of Wind at 9 a.m.	
	Morning.	Noon.	Night.	Morning.	Noon.	Night.		
1	50°	54°	48°	30.14	30.10	—	S.	Fair, generally gloomy. Rain a.m. and p.m.

### PRESENTATION OF THE PRESIDENT OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

An interesting event in the history of photographic societies occurred on the evening of Thursday last, at the Annual Dinner of the South London Photographic Society, when a presentation was made to the Rev. F. F. Statham, M.A., the President of the Society. For nearly sixteen years (ever since the birth of the Society, in May, 1859), Mr. Statham has presided over its meetings with an assiduity and constancy of attendance scarcely equalled by that of any other member of the society. Originally, and for a brief time, an offshoot of a literary society in the South of London, the first independent meetings of the Society were held in a school-room connected with St. Peter's Church, Walworth, of which Mr. Statham is the Rector, and he presided over the meetings of the Society there. By-and-bye a gradual preponderance of members not resident over the water rendered a more central position desirable, and the meetings were held in the City of London Institute in Leadenhall Street, and Mr. Statham, notwithstanding that society left the South, continued his presidency there, and also during its further migrations up to the present time. Mr. Statham is not a photographer, but an ardent lover of science, and a highly accomplished gentleman, with a large, kindly, genial nature, delighting in every opportunity of promoting the culture and happiness of those with whom by choice or chance he is thrown into contact. It is in virtue of this largeness of heart and high culture that he holds the presidency of the South London Photographic Society, and it is greatly due to his presidency that the Society has continued in existence and has steadily grown in activity and in influence, whilst other suburban societies have become extinct. A "sweet nature, gilded by the gracious gleam of letters"—to borrow a phrase from the Laureate—presiding with a benign courtesy, with a bearing at once bright and cheerful, and a happy suggestiveness often more valuable than precise practical knowledge, have given to the monthly gatherings more of the character of friendly re-unions than formal meetings. The President's tenure of office in the South London Society is annual, but no doubt has ever entered into the mind of a single member as to the naturalness or fitness of the re-election of Mr. Statham. The project once mooted of presenting to him the admirable life-size enlargement of the Autotype Company from Mr. Blanchard's fine negative, skilfully coloured in oil, was at once endorsed by every member of the Society; and the project was so privately carried out that until, with a fine dramatic touch, the portrait was uncovered at the close of Mr. Hughes' speech, the President himself knew nothing of it, and was the only one in the room to whom it was a surprise. How glad a surprise we need not attempt to indicate. The occasion was a pleasant and satisfactory one to all. No society could have a better President, and none could better appreciate their privilege or show stronger fealty to a worthy chief.

### PHOTOGRAPHIC DESIGNS FOR ORNAMENTING WOOD.

We referred recently to the various surfaces suitable for photographic purposes, to which, however, they had rarely been applied, mentioning, amongst others, white woods of fine texture. A specification of a patent taken some time ago describes the special application of photography to the production of ornamental designs on wood. The specification is chiefly devoted to means of printing directly upon the surface of the wood, veneers being used to simplify manipulation, and admit of polishing with the remainder of the wood, into the surface of which the pieces containing the photographic designs may be inlaid. It is obvious that many very pleasing effects in fancy cabinet work may be produced by the aid of photographic designs, whether of pictorial or decorative subjects, which could not so readily be produced by any other method. The use of carbon prints transferred to the surface of the wood, and varnished, or French polished, would probably be preferable to the methods described in the specification, which is as follows:—

"Our invention relates to certain improvements in the means or method of producing photographic pictures or designs of any description on or in the surface of veneers and solid wood, and in applying such photographed designs or devices to every required class of cabinet work, fancy wood articles, to walls, house panelling, and other such like decorative purposes. In order to effect these objects we take a piece of even-grained veneer suitable to the article we desire to ornament, and plane both sides of the same with a toothed iron plane until it is of an uniform thickness. One side we leave in this rough state so as to be ready for treatment with glue or other adhesive solution. The other side we scrape and rub with glass-paper so as to remove all the marks of the plane, leaving a perfectly smooth surface, which we damp with water or some other suitable liquid in order to cause the grain of the wood to rise. We then allow the wood to gradually dry, and again we rub with very fine glass-paper. We again repeat the damping and rubbing until the wood grain ceases to rise. We now apply to the surface with a sponge, brush, or blotting pad a solution of chloride of sodium or chloride of barium (the former by preference), and gradually dry the same, when it is ready to be sensitized with a solution of nitrate of silver. We desire this silver solution not only to come in contact with the surface of the wood (as is the case with photographs printed on wood for engraving purposes), but to penetrate to some extent into it, as hereafter described. We now place the photographic negative on the sensitized wood, and the printing is then performed in precisely the same manner as photographs on paper.

"The process of laying the veneers is as follows:—We take a piece of wood veneer on which a suitable photographic picture or design has been imprinted, and cut it to the shape we consider requisite for the subject in hand. We then prepare the toothed or rough surface (previously referred to), and glue the same or otherwise cause its adhesion into the centre or other part of the article we wish to decorate by placing it under a heated piece of smooth metal or wood, and compressing the same with screws in a calbench or in any other usual way of fixing veneer. When sufficiently dry and hard we fill up the surroundings of the table top, panel, or other article by gluing or cementing around and abutting up to the photographic design veneers of walnut or other suitable woods (with or without photographic devices thereon). After allowing the same to dry we plane off and smooth down to the surface of the photographic picture (or pictures). We then proceed to polish both the surroundings and the picture (or pictures) with transparent French polish, which has the effect of hardening by penetration the fibres of the wood, and materially aids in bringing out all the details,

Our object in permitting the silver solution to penetrate into the pores of the wood is that thereby the light acting on the chloride of silver darkens it so far into the fibre of the wood as the silver has penetrated; for, as a part of the surface of the picture may wear away in time, as some parts necessarily must which are very much exposed and used (such as a table top, for example), yet the greater part of the detail of the photograph remains.

"We also apply our invention as follows:—We take a piece of veneer which has a picture, design, portrait, image, or view photographed thereon. We lay it upon a walnut or other veneer which has been cut sufficiently large to cover the surface of any given article. We then with a very fine saw cut through both veneers to the line or figure required. We take away the under piece, and allow the top or photographed veneer to drop into its place, for since both would be cut by one and the same operation, it would also follow that one would fit securely into the other. We then glue or otherwise attach a piece of paper over that side on which the photographic picture or design is printed. It can then be kept already prepared to glue in or attach to any article requiring ornamentation, either furniture already manufactured or in course of manufacture, also to be applied to walls or interiors of houses, and for panelling and other decorative purposes.

"In regard to solid woods or surfaces which have previously been veneered, we prepare the surface as before described, and print the photographic pictures or designs in the same manner as for veneers.

"The invention is, of course, equally applicable to the production of pictures to be framed and glazed.

"Having now described the nature of our said invention, and the manner in which the same is to be performed, we would remark, in conclusion, that we do not limit or restrict ourselves to the precise details expressed, as it is obvious that the means or methods described for effecting the objects of the invention may be varied or modified without departing in any way from its principles either in reference to chemical or mechanical details; but what we claim and desire to be secured to us by the herein in part recited Letters Patent consists,—

"Firstly. In the improved means of producing photographic pictures or designs of any kind on veneers and solid wood.

"And, secondly. In the improved means of applying photographic productions to cabinet work, furniture, fancy wood articles, and other decorative purposes, all substantially as herein specified."

#### AMERICAN CORRESPONDENCE.

##### BLISTERS—BATH RENOVATION MADE EASY AND SURE.

*Blisters.*—Are you troubled with blisters? This query caused a long discussion at our Chicago Convention, and Mr. Hearn, author of the "Practical Printer," treats of it as follows:—

"In the case of the writer, he found that the blisters generally occurred in the fixing bath after the prints had got about one-half fixed, and then, by the time they were ready to be removed, they would either altogether be covered with innumerable myriads of infinitesimal blisters, or else they would partly be treated with very large ones; in either case drying down very badly. The usual remedies for such cases (such as weakening gradually the strength of the hypo, and placing the prints after they were fixed in a bath of chloride of sodium) were tried, but without much success, for after the prints had once blistered it seemed to be an impossibility to remove them effectually, especially so when they were very large or at all numerous.

"The writer was using at the time, in his fixing bath, one part of a saturated solution of hypo to five parts of water, and fixing from eight to ten minutes. Upon experimenting, it was found that if the prints were placed in an alum bath before fixing (saturated solution of alum one part, water five parts) they would often be without the blisters; yet, as they would occasionally

have them, other means were resorted to, which eventually resulted successfully in connection with the alum bath before fixing: it was that of reducing the density of the soda solution down from one-fifth to one-tenth and even one-twelfth, and fixing a proportionally longer time.

"From the above it was ascertained that the double paper should be subjected to mild treatment in the fixing bath, and also that the albumen softens and, consequently, blisters in the hypo, and thus the necessity of some substance in the hypo bath that would coagulate the albumen and prevent its blistering. For this purpose common alum has been used, but is generally, almost immediately, abandoned as an impractical ingredient, on account of the danger of its liberating sulphur, and the disastrous results arising thereby. Mr. H. T. Anthony advised the use of nitrate of alumina in the fixing bath, as it answers the same purpose as the alum without the disadvantages of the latter, and upon trial it proved practically to be an excellent chemical. However, placing the prints for a few minutes in an alum bath before fixing, and rinsing them once or twice with fresh water before they are removed to the fixing bath, answers the purpose equally as well as the addition of other ingredients to the hypo bath would, without any danger of bad effects resulting therefrom.

"But when blistering of the paper occurs before the prints are placed in the hypo bath, and not afterwards, then a far different reason from the above is the cause. For instance: Let us suppose that, after the paper is printed, the prints are acidified in lukewarm water, washed in cold water, toned in a bath of different temperature from either the above (generally blood-warm), placed in a dense and cold salt solution, fixed in a cold and strong hypo solution, soaked in another bath of salt water, probably also of a different temperature as well as different density from what the fixing bath itself was, and then perhaps, after the prints had been soaking in this salt-water bath for ten minutes or so, they are suddenly transferred to the washing tank, where the water is probably quite cold, as well as being of a much lighter density than the preceding bath.

"Can any printer expect that the paper will undergo such treatment as the above and not blister? Why, the printer ought to consider himself fortunate that nothing worse befalls his prints rather than to complain otherwise; and yet the above-described method in which the paper is treated after printing is precisely the way in which the double paper is washed by the majority of photographic printers to-day.

Such slight (?) things are not considered as worthy of the attention of the printer, and hence he utterly ignores them; but rather on the contrary, is it not a matter of some surprise that the tender surface of the albumen paper can undergo such treatment at all? I think it is.

"To judge of what temperature to have the solutions in which the prints are placed, take for a guide, the temperature of the water by which the final washing is to be accomplished, and have all of the solutions as near that as is possible, a thing which is very easily done, by using that water as taken from the faucet to do the washing in. In the winter season great care should be taken about using the water too cold.

"As to the toning bath, do not warm it a particle, as is often done to facilitate the working of it, but let the bottle in which the toning is kept be placed in a cool place, and that will also be the best way to use the toning bath, for with a warm bath the tones are never as good as they are with a cool bath, but not too cold.

"As to the density of the salt solution after fixing, make up the bath so that, upon tasting, it will give a pleasant saline taste to the tongue, and, after the prints have remained in here full ten minutes, reduce the solution very gradually down to the density of the tap water.

"I hope that the above may be the source of extricating some brother photographic printer from his troubles."

*Bath Renovated Made Easy and Sure.*—Mr. B. W. Kilburn says, on this subject:—

"There is a great deal of stumbling among photographers in the matter of renovating an overworked bath, and a great deal of time lost in bringing about what is usually an imperfect result. I do not advocate frequent "doctoring," but there are times when the bath becomes so charged with ether, alcohol, and organic matter that, like an overloaded stomach, it fails to do its duty, and it must needs have attention. When that is the case, I find the following method the easiest and the best; and I am not yet quite sure but what my bath works better after I have thus heated it than it did originally.

"Proceed as follows:—Empty the bath solution into a wide-

mouth bottle, large enough to hold twice as much solution as your bath contains. Now place some bicarbonate of soda upon a clean glass plate, break up the lumps with a case-knife or spatula, and add the soda to the solution very gradually, stirring with a stick or a glass rod constantly. Precipitation begins as soon as you add the soda. The solution will boil and simmer, and rise to the mouth of the bottle, perhaps. Should it do the latter, stir more rapidly among the bubbles which rise to the top, and blow upon them violently, when the boiling will subside. With proper care, none of the solution need be lost. Continue thus to add the soda, and stir until all action ceases, and then set aside until the fluid portion is perfectly clear. Now pour off the fluid carefully and slowly, and add fresh water. This 'washing,' *i.e.*, pouring off and adding fresh water, should be repeated say a dozen times, until the precipitate, which is carbonate of silver, is thoroughly cleansed and free from smell. Now to this washed precipitate carefully add C. P. nitric acid, shaking gradually. Continue this until all but a few grains of the carbonate is dissolved. Now add water, testing with the hydrometer until you obtain the strength of solution desired for your bath. Then filter, test with litmus-paper, and, if acid, add bicarbonate of soda until the bath becomes barely neutral. If not acid, make it slightly so by adding C. P. nitric acid. No iodizing is necessary in such cases."

Perhaps you have enough this time. We are looking for the YEAR-BOOK anxiously, laden with good things as it always is. Wishing you a very happy new-year, I am truly yours,  
EDWARD L. WILSON.

### ACCESSORY EXPOSURE OF THE SENSITIVE PLATE.

BY BENJAMIN WYLES.\*

As long as babies continue to vex the spirit of the photographer, it is probable that perplexed and much-enduring individual will be interested in anything offering a possibility of shortening the camera exposure. Indeed, even for others than restless juveniles the shorter the exposure the better, if other things remain equal. Hence nostrums and quackeries innumerable have been offered, and much legitimate effort has been put forth in connection with the chemical, optical, and mechanical departments of our art-science to obtain this desirable consummation.

One of the latest claimants for popular favour (though not entirely new) is found in allowing actinic light in some form to impinge upon the plate either as a pre- or post-exposure, or in some cases simultaneously with the action of the picture on the plate. Many of the ways suggested of applying this extra light, however, are unmanageable in their nature and variable in their results; hence it is not surprising that some difference in the opinions as to their efficiency at all should exist. For instance, it might be anticipated that by the use of opal-glass before the lens the amount of light transmitted would much depend upon the angular relations of the lens to the window. If the instrument pointed away from the light little would enter the camera, whereas if turned more towards the windows the effect would rapidly increase; hence a variable result would accrue even with an exposure apparently similar. In practice this was found to be the case. Although the result in one instance might be excellent, the next plate would, perhaps, be fogged. It was impossible to be sure of the maximum good effect without sometimes going too far. The use of a gas jet in the dark room was thought of with more promise of certainty. As, however, gas is a variable product, and the pressure frequently altered, a more uniform source is desirable. No great step is needed to find one in the standard by which the illuminating power of gas itself is measured. A sperm or wax candle will give all that is required. It is handy, definite, and not over expensive. The kind that chanced to be tried by the writer is known as "Price's Ceylon wax."

An uniform source of light obtained, it remains to test how many seconds' exposure the plate will bear without

danger to fog. A few experiments showed that in my dark room ten seconds' exposure at a distance of three feet gave the maximum of good effect. I apprehend that in other rooms the amount would vary with the amount of actinic light already present there, as, probably, no dark rooms are actually "dark" in the absolute sense.

Some discrepancy exists in the accounts of the benefit derived by an accessory exposure. Some claim for it as great a reduction as half or even three-fourths of the whole. I am not inclined to be so sanguine. A reduction of from twenty-five to thirty-five per cent. seems nearer the mark, perhaps; but such a saving in time is not to be despised when a group of youngsters, graduated from one year upwards, have to be taken on a November afternoon.

The question of a pre- or post-exposure is one with which the writer has not much troubled himself, being generally content with the former. In one or two comparative experiments, however, made to test this matter, the preponderance was very considerably in favour of the pre-exposure. It is common enough at a railway station to see six or eight men engaged in starting a truck they wish to move; once started, however, two or three of those same men will easily suffice to propel it. Again: various seeds are soaked in water before being sown, in order to start them growing more quickly. Indeed, throughout nature a portion of force is spent in overcoming inertia before the continuance of that force can be utilized. It is probable this is the explanation of the utility of a pre-exposure of the sensitive plate.

One or two considerations should be borne in mind by experimentalists in this direction. With a bath overworked, surcharged with ether and alcohol, and already giving flat results bordering on fog, it is not likely that much good result will be found. Again: in portraiture, where softness, delicacy, and half-tone are desiderated, the use of accessory light is far more indicated than in reproductions or copies of "still life," where vigour of high light and firmness of shadow are looked for. Like all other powers, it should be used with judgment, and with reference to the effect desired to be produced.

#### LANTERN IMPROVEMENTS.

DEAR SIR,—The Englishman's fire-side is everywhere proverbial for its comforts; yet the long winter evenings, even in so cozy a retreat as this, would prove dreary without appropriate amusements. Thanks to photography, without moving from one's chair, journeys round the world may be made by viewing facsimiles of interesting scenes in various climes. Aided by the explanation of an intelligent and well-read exhibitor, nothing can be more instructive to the young, or interesting to the old. There are no means of showing such pictures in so lifelike a manner as by the aid of a good dissolving view apparatus. I warn those of your readers whom it may concern, that it is time to commence preparations. A true sportsman, before starting on a campaign, takes care minutely to examine his arms, and see that he has sufficient munitions for his purposes. An exhibitor who hopes to render his services acceptable must make this plan a duty; and it is the tyro's best method of making himself acquainted with the uses and action of the various parts of his apparatus. It should be done methodically.

With a view of rendering assistance to beginners, allow me to suggest that the bodies of the lanterns first be taken into consideration. Let them be well cleaned. If made of wood, see that the panels have not become cracked or warped; if of tin, that they are not bulged, and that the doors act without noise. A little French polish or black Japan, as the case may be, will, if needed, greatly improve

\* A communication to the Manchester Photographic Society.

their appearance. The latter is used as a varnish, and the tin work should be made warm. The nozzles should next be examined, and the lenses taken out and cleaned. A few drops of spirits of wine and an old silk handkerchief will greatly aid this operation. The condensers should be kept in boxes, and only adjusted to the lanterns when required for use; otherwise they are liable to be spoilt by getting scratched.

Having thus far got everything in order, we now see to the lighting apparatus. If lamps are used, having been well cleaned, see that they are perfect, and that their parts act freely, otherwise fingers are likely to be burned, and everything go wrong. The glass chimneys should be of the best. There is a common sort sold which are worse than useless. As accidents may happen, it is best always to carry a double set. If gas is to be used, the bags should be inflated by means of a pair of bellows, placed between their pressure-boards, and the proper weight applied. Then, on a piece of stick standing upright on the floor, mark the highest angle formed by the pressure-boards. Leave them for an hour. If, after that time, on applying the stick, it is found that the angle remains at the same height, the bags may be considered trustworthy. Blow-pipes and tubing should be blown through, to test if they be free. This is especially necessary with the rigid ones, as they accumulate rust from the wire-coil inside them; also, in time, they are apt to become brittle and cracked. A good way to preserve their flexibility is to give them occasionally two or three coats of spirit varnish of a soft nature, applied with a sponge. Care should be taken that unions are not subjected to rough usage, otherwise they might prove worthless. A washer made of leather is the best remedy. A sufficient quantity of materials used for lighting, making gas, and other little et ceteras, should always be kept in readiness.

JAMES MARTIN.

5, Clarence Place, Ilfracombe.

## Proceedings of Societies.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

#### *Annual Dinner.*

THE Annual Dinner of this Society was eaten at the Cafe Royal, Regent Street, on Thursday, the 17th inst., the Rev. F. F. Statham, M.A., President, occupying the chair, and Mr. Sebastian Davis and Mr. Jabez Hughes the two vice-chairs. The gathering was very large, as it was known to the members that a presentation to the President was to be made in the course of the evening.

After a capital dinner, and the usual loyal toasts,

MR. JABEZ HUGHES, in a genial and effective speech, introduced the subject of the presentation, and expressed his gratification that such an unusually large and goodly company was present, giving especial force to the sentiment which had inspired the members unanimously in regard to the presentation. Only some present could remember how fifteen years ago a small band used to meet together on the other side of the water, for the purpose of cultivating the art of photography. The society was then connected with a literary institute, from which, however, it afterwards separated, and continued its meetings in the school-room kindly lent for that purpose by the President. Since then it had removed first to the east, then to the central portion of London, and afterwards to the west. Throughout its career the members had worked hard, had seen their numbers gradually increase, and although older societies had died out, there were no signs of decay in the South London Society—(applause)—which, it might be said truly, was never in a more healthy state than at the present time. How, then, did it happen that this society had none of the elements which destroyed other societies? He (Mr. Hughes) was not able to answer the question fully; but unquestionably there was one element which had much to do with its success. It had had from the very first for its president a gentleman of high culture, full of information, earnest in promoting their interests, and ever ready to give his attention to the humblest as well as the ablest of the members. This had gone on year after year, in

season and out of season; the president had been always at his post, always ready with his winning smile, and with his wise counsel to help and support the society. Notwithstanding his special duties, he had continued year after year, for fifteen years, to assist the society in this way, and at the end of that time he was more heartily loved than he had ever been. (Applause.) No man could have better discharged the duties of president than had Mr. Statham. He attended the out-door excursions; as if that was not enough, he invited every year the members to partake of his hospitality, on which occasions were spent an afternoon and evening as pleasant as an English gentleman could offer to his friends. It was to do honour to Mr. Statham that the large gathering had assembled there that night. Mr. Statham would remember that some time ago he sat for his portrait to Mr. Valentine Blanchard, copies of which it had been determined to distribute amongst the members as the presentation picture of the year. This portrait had, however, been enlarged to life-size by the Autotype Company and painted in oils; and when it was exhibited at the Technical Exhibition of the Society, it was felt that it ought not to be allowed to go astray in the world, but ought to be in the possession of Mr. Statham himself. It was determined to procure this portrait, and the members of the society desired that night to ask their President to accept it as a small and insignificant recognition of the services he had rendered to the society. (Applause.) Accompanying the picture was a memorial on vellum, which, to a certain extent, expressed the sentiments with which the members were actuated in presenting the testimonial. They did not attach any value to the picture itself, excepting as a token of the deep and sincere affection they owed to the gentleman to whom it was presented.

The portrait, which was an exceedingly fine work of art, and an admirable likeness, was then uncovered, and the memorial presented to Mr. Statham, after which the health of the latter was enthusiastically drunk.

MR. STATHAM, in reply, said he was most completely and thoroughly taken by surprise, and felt he was quite unable adequately to express his appreciation of the kindness which had been manifested towards him. He had not the remotest idea of what was about to be done, and appreciating, as he did, most deeply the testimonial offered to him, he was quite incompetent to give expression to the feelings which animated his breast. He would say, at all events, that the gift was one which any man (even he who had served his country for long years) might be proud to receive, but one which he thought far exceeded his deserts. From the first this society had had the right elements within it, for it was a band of friends associated together by a common love for artistic pursuits, and the fact of being animated by one feeling sufficed to explain that success to which Mr. Hughes had referred. There had never been any ill-will or jealousy in the society, because the members had always had an affectionate regard for each other, and thus were not likely to quarrel. If there was any merit due to himself, it was that he had endeavoured to allow everyone to have an opportunity of putting forth his opinions, and the youngest member had always felt he could utter his thoughts without any restraint. It had never occurred to him that there had been any tendency on the part of any one to exalt himself at the expense of another, and this he could not help thinking should be the characteristic of all searchers after truth. In regard to the society, he would say that some of the most enduring pleasures of his life were connected with it. He did hope to live a few years longer, and though he did not profess to be a brilliant man, he did strive to be a useful one in his day and generation. He was very glad to know the testimonial was accompanied by a memorial. Had it not been so, he should have asked for some expression of feeling, that his descendants might be enabled to say he was a man who had borne an honourable name. (Applause.) He was one of the descendants of the ejected Nonconformist ministers of Charles II., and long before that could trace back his family for several generations to the time of Richard II. The family name had never been disgraced, and he did hope that this honourable feeling would be carried down to following generations. (Applause.) The testimonial was to him far more valuable than any piece of plate, and he hoped his children and his children's children would preserve it as it deserved to be. (Applause.)

DR. MANN, in proposing "Success to the South London Photographic Society," said he did so with peculiar pleasure, because the society not only knew how to secure a good president, but knew also how to appreciate him.

MR. EDWIN COCKINO, hon. sec., responded. The Society had done much in the way of introducing what was new and useful.

During the past year a considerable advance had been made. The members had increased, and there was every prospect of a great future before the Society. That future, however, depended to a great extent upon the members themselves, and he hoped every exertion would be put forward to make the Society something more than it had ever been before. (Hear, hear.)

The CHAIRMAN then proposed "Success to the Photographic Society of Great Britain." In the course of his remarks he alluded to the important part which photography would play in connection with scientific discoveries. Especially was this seen in the recent observations of the transit of Venus. Hitherto astronomers had been much puzzled by the peculiar shape which the planet assumed in commencing its passage across the disc of the sun. Instead of being of a circular form, it somehow dropped, and assumed the shape of a pear. Photography, however, noticed no such appearance, and thus the peculiar shape was conjectured simply to arise from the infirmity of our visual organs. Should this turn out to be correct, the discovery would prove the most remarkable one which had been made for some time past, and he mentioned the fact to show that no one could tell what important part photography might not play in the science of the future. In regard to Photographic Societies generally, he would say that he had always looked upon the proceedings of the London Photographic Society with the utmost interest. There had, perhaps, been a little more activity than usual in the Society; but, after all, it was better to have boiling water than cold. (Laughter.) If there had been differences, these would subside in time, and he believed all would come right. (Hear, hear.)

Mr. SPILLER (President of the Photographic Society), whose name was associated with the toast, observed that he had to follow a line of presidents among whom had been Sir Charles Eastlake, Lord Chief-Baron Pollock, and Mr. Glaisher; and the crown had now descended upon himself. He took a deep interest in the society, and had had some years' experience of its working, and should be proud if, in holding his present office, he was enabled to be of any service (hear, hear). He was present that evening as a humble member of the South London Society, and was glad to recognise many who were members of both societies. In reference to the special event of the evening, Mr. Spiller said that one of the contributions sent in to the annual exhibition of the Photographic Society was the magnificent portrait at the end of the room. He could hardly tell the pleasure with which he looked upon it, both as a work of art and as a likeness; and it was consequently with greater regret that he found he could not give it the place of honour without transgressing one of the rules which confined the exhibition to untouched photography. In conclusion, Mr. Spiller referred to the important labours which were being carried on by Captain Abney, Lord Lindsay, and others in connection with the transit of Venus.

Mr. S. DAVIS then, in a thoughtful speech, proposed the toast of "Amateur and Professional Photography," coupling with the former the name of Mr. Frank Howard, and with the latter Mr. S. Fry and Mr. Bird.

Mr. FRANK HOWARD, in responding on behalf of "Amateur Photography," expressed his regret that the ranks of the amateur photographers did not increase in number. The labours of amateurs had been of the utmost value in experimenting and in testing the value of new processes, and they had been able to devote an amount of time in this direction which the professional man found impossible. Again, if it were not for amateurs, Mr. Howard remarked, with some humour, who would buy all the highly-finished and elaborate apparatus which enterprising manufacturers were constantly introducing? (Laughter.)

Mr. S. FRY observed that photographers, in respect to such work as was exhibited that evening, were rather hardly used. A coloured portrait, no matter how beautiful, could not be admitted into a photographic exhibition, because it was not photography; while on the other hand, were it to be sent to the Royal Academy, the latter would say, "This is not art; we cannot have it here" (laughter). And so, between the two fires, the photographer came off badly. In conclusion, Mr. Fry dwelt upon the value of the South London Photographic Society in regard to the attention it had always devoted to art.

Mr. WALTER BIRD, in responding for commercial photography, referred to the importance of obtaining permanency in photography, an aim which the firm he was associated with made pre-eminent effort to secure. After a brief but able speech,

The CHAIRMAN proposed the health of the "Visitors," coupling with the toasts the names of Dr. Mann, Mr. Matthew Whiting, and Mr. Baynham Jones.

Dr. MANN, in reply, referred to the phenomenon of the "black

drop" in the transit of Venus, of which mention has been made by the Chairman. He (Dr. Mann) was not sure that photography would give the explanation, for, in examining some apparatus with the Astronomer-Royal, he had in some cases seen the "black drop," while in others it had been absent. The true value of photography to science consisted, he thought, in the fact that every observation was permanent, and could be referred to again and again. Had Captain Cook's observation of the last transit of Venus been recorded by photography, there would have been no necessity for the immense trouble which had recently been taken. Dr. Mann then alluded to the coolness and accuracy displayed by Captain Abney in using an instrument by which sixty photographs were taken, and which was so carefully timed as to begin and end with the passage of the planet across the sun's disc; and concluded by expressing the pleasure he felt at being present that evening.

The toast of the "Press," coupled with the names of Messrs. Wharton Simpson, J. T. Taylor, William Sawyer, and C. Pearce, was given and duly acknowledged.

Various songs and glees, sung by the members, added to the brightness of the festivity. Mr. Howard sang a photographic comic song, detailing the mishaps with dry plates of that unfortunate photographer whose long sufferings he has before recorded. Mr. Tully gave some capital comic songs. The evening was in every way a success.

#### MANCHESTER PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting of this Society was held at the Memorial Hall, on Thursday evening, the 10th inst, Mr. THOMAS HATWOOD, Vice-President, in the chair.

After the routine business, Mr. BENJAMIN WYLES, of Southport, read a short paper "On Accessory Exposure of the Sensitive Plate" (see page 615), and exhibited a number of very fine specimens of card portraits in illustration of his remarks. In reply to a question by the Secretary,

Mr. WYLES said he had found the effect to be greater when the plate had been exposed to light before, rather than after, exposure in the camera.

Mr. FRANKLAND exhibited two fine specimens of highly-glazed portraiture by Mr. Sarony.

Mr. POLLITT showed an enlarged view of the Pyramids, 15 by 12, from one of Professor Piazzzi Smyth's negatives, 2½ by 2½. This was an excellent specimen of enlarging, being very perfect and sharp.

Mr. NOTON said he had been trying to make some nitro-glucose, and thought he had succeeded in producing 258 grains of that substance. The uncertainty of obtaining chemically-pure monohydrated nitric acid, and the conditions as to water not being present, had caused him to put off the attempt to a more favourable opportunity; but Mr. W. B. Bolton's two communications in *The British Journal* for August last had reminded him of a memorandum he had made about four years ago at the foot of page 128 of *The British Journal Almanac* for 1869, and that he had not yet answered the query alluded to, viz.—Why not use saltpetre instead of nitric acid? The experiment was tried yesterday, and the result was on the table. Some saltpetre was rubbed to a fine powder and dried in the oven. Some lump sugar was treated in the same way. The sulphuric acid was put out of doors to get cold. The saltpetre was put into a white preserve jar, being surrounded with cold water in a wash-hand basin—all out of doors. When the sulphuric acid was put to the saltpetre a very stiff mixture was made; more acid being added till sufficiently fluid, but still rather stiff. The dry sugar powder was dusted on, and gradually stirred in with the glass rod, no red fumes of nitrous acid being produced, and no colour. The sugar was immediately changed, and the mixture became viscous. After standing some time covered with a glass plate to keep in the nitric acid fumes (which were very moderate in comparison with those given off in making gun-cotton with saltpetre, the temperature being 100 degrees lower at least) a small portion was dropped in to cold water; the sulphate of potash gradually dissolved away, leaving the nitro-glucose in the form of a white powder. The large mixture was then thinned considerably with cold water stirred in, and all put to filter. The nitro-glucose, being still in the form of a white powder (like starch in cold water), was well washed on the filter. The top of the paper was then got together, all lifted out of the funnel, and held in warm water; this united the particles into a pasty mass. It was now freed from the paper, pulled into shreds, and kneaded under warm water for some time in making a second lot of nitro-glucose it was intended to put the

sulphuric acid into the jar first, and then stir in the saltpetre and sugar, previously ground fine and thoroughly mixed together. If it turn out that the nitro-glucose made by the aid of saltpetre in lieu of the chemically-pure monohydrated nitric acid is good, and possesses the extraordinary properties mentioned by Dr. Monckhoven, a great impediment to its more extensive use will have been removed.

Mr. Noton exhibited a pair of small blowing engines, of his own manufacture, in the tea room. These engines excited a good deal of interest in the mechanically-inclined members.

The usual complimentary votes were passed, and the meeting was then adjourned.

## Talk in the Studio.

**WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.**—The next ordinary meeting of the above society will be held on Monday evening, the 28th December, at half-past seven, at Leuchter's Rooms, Ivegate, Bradford. Subject—Passing of Rules, &c. Mr. Manley, of Brighouse, will also give a Lantern Exhibition, to which members are invited to introduce a friend (lady or gentleman).

**PREPARING PLATES BY DAYLIGHT.**—The *American Chemist* says:—"Dry plates can be prepared by daylight, according to Prof. C. F. Himes, as follows:—"Glass plates coated with ordinary brown-iodized negative collodion are sensitized in the usual argentic nitrate bath, in bright daylight, and are then thoroughly rinsed in distilled water to remove the larger portion of adhering silver solution. They are then flowed with a five per cent. solution of potassic iodide, or are exposed to the action of sunlight for several hours, and then dried. Such plates are insensitve to light, and may be made sensitive by immersing them in the dark in a solution of tannin, fifteen grains to the ounce of water, for a few minutes. Being then dried they will remain sensitive for months."

## To Correspondents.

THE YEAR-BOOK OF PHOTOGRAPHY FOR 1875 will be ready in a few days. Besides the usual contents, consisting of a resume of the practical improvements of the past year, the present issue contains a larger number of original contributions than any former annual. Amongst the contributions will be found articles by Dr. Diamond, Dr. Anthony, Dr. Vogel, Dr. Liesegang, Dr. Van Monckhoven, Dr. Maidstone Smith, Dr. Phipson, Dr. Nicol, Col. Stuart Wortley, Capt. Abney, Capt. Turton, Capt. Stretton, Messrs. H. P. Robinson, Adam-Salomon, Blanchard, Dallmeyer, Mayland, Werge, Cherrill, O. G. Rejlander, Pritchard, Fry, Bedford, Window, Bovey, Spiller, Faulkner, Eliot, Slingsby, Heighway, Speucer, Beattie, Birtou, Tuany, Neilsou, Bruce, Perriu, Tudor Williams, Penny, Dunsday, Watson, Croughton, Briggs, Sydney Smyth, T. Gulliver, Kennett, Eve, Wilkinson, Borland, Cocking, Gregson, Gregg, Sutcliffe, Willis, Ferranti, Bool, Hedges, Mitchell, Beasley, Hooper, Rivot, Aldridge, Huuter, Johnston, Martin, Walter, Hudson, Wilson, Alexander, Gough, Brier, Tedrake, Stodart, Young, Wilstenholme, Fernely, Burgess, Asher, Pearce, Edwards, Gillard, Pumphrey, and many others.

**KENNETT'S GELATINE PELLICLE.**—Notwithstanding the notification in our last that the discussion on this subject must for the present cease, we have received three more letters on the subject, which, if printed, would occupy nearly three columns. The subject is an interesting one, but the exigencies of space demand that for the present it must rest. When the personal elements evoked in the discussion have had time to subside, we shall have pleasure in hearing further testimony on the practical working of gelatine. We briefly give a few words from each of our correspondents, in order to satisfy what some of them regard as the requirements of justice. "A Worker" writes to urge that the use of a *nom de plume* in no way affects his facts, which, in justice to Messrs. Maddox and Johnston, whose work he contends is embodied in Mr. Kennett's specification, it was important should have attention called to them. He further quotes a passage from a contemporary journal, dated November 7, 1873,

pointing out that the information promised a few months previously on behalf of Mr. Kennett was withheld because of that gentleman's interest in a commercial enterprise based on the gelatinobromide process. Captain Turton sends us a long and interesting letter, which we regret we cannot, after our last week's announcement, insert at present. He thinks Mr. Kennett is bound, after his prediction as to his process superseding all the rapid dry plates, to provide dry plates which may be tried against dry plates, and undertakes to give them a fair test against wet plates and dry collodion plates, especially the Wortley plates, which have given him fine and quick results. "J. S. D." makes a vigorous protest against those who attack the use of initials, or of a *nom de guerre*, in journalistic correspondence. "A provable fact is none the less a fact," he observes, "because it is only signed X. Y. Z., or more a fact if signed by a score of well-known names. If the only authority for a statement of fact be that of the writer of the letter, then he would be bound to append his name to his statement; but if he refer to other accessible authority, the presence or absence of a real name is of no importance whatever; and it is foolish in the extreme to pretend that the statement of a fact under a *nom de plume* is either cowardly or unfair." After citing some illustrations, he adds: "'A Worker' has given his authorities for challenging Mr. Kennett's patent, and in doing so has acted fairly—so fairly that he has left it clear that his authorities are insufficient. Mr. Kennett's patent, if I understand rightly, does not rest upon any of the details quoted by 'A Worker' from the processes of Dr. Maddox and Mr. Johnston. In describing his process before the Photographic Society, in June last, Mr. Kennett distinctly acknowledged the labours of Dr. Maddox and others. He described the process of making and washing the gelatine emulsion, not as part of the patent, and finally added that after this 'his invention came in,' and that his invention consisted in drying the emulsion, and so making it keep indefinitely in the form of a pellicle. Until then, gelatine emulsions could not be kept; and to provide a means of successful preservation is, I presume, really the point of the patent. At any rate, it is clear that all that Mr. Johnston, or Dr. Maddox, or any one else, did before the patent, every one else may do still."

J. D. L.—The pyrogallic has either been of imperfect quality, or it has been previously exposed to the air. Pure fresh pyrogallic acid dissolved in alcohol will, as a rule, keep well. When it burns nearly black, as you describe, it is unfit for use. An aqueous solution with citric acid will often keep well; but it can only be used, of course, in acid development. 2. The best mode of repairing your waterproof covering will be with pieces of similar material made to adhere with a paste or varnish of india-rubber dissolved in bisulphide of carbon.

KING.—We do not know of any work on the subject of candle manufacture, nor on the manufacture of violin strings.

R. D.—The example slide you have forwarded is not suitable for the magic lantern, as, from its general opacity, it would intercept too much light. A transparency for the lantern should not be too dense in any part, and clear and transparent in the lights. The bath should be working well, giving clean, delicate, and brilliant images. The development should not be carried too far. The toning may be effected with gold, or with a solution of sulphide of ammonium.

D. E. R.—No, of course not iodized collodion; simply a plain collodion of good body, giving a tough film. It must be quite dry before applying the gelatine.

W. R. E. M.—The chief cause of risk in using collodion pictures for coloured work is, the use of an unsuitable sample of collodion. If a very horny sample is used, it is apt to split; and if a very old and decomposed sample is used, the film will sometimes split. Prolonged development will also tend to produce splitting and peeling. We have repeatedly given formulæ for matt varnishes, but if you have no experience in making varnishes, it will be wiser to buy one of those already in the market. 2. It would be quite impossible in this column to give you formulæ and instructions for producing porcelain pictures in the camera. We have published many articles on the subject. Possibly the best formulæ are those of Mr. Burgess for the eburneum process. Your own formula is pretty good, but faulty in some particulars: the use, for instance, of the hydrochloric acid is unwise. But you must be quite prepared for the fact that it is rarely possible to produce on collodion a picture as brilliant as a good paper print.

**EAST LIGHT.**—An east light may be made to give very good portraits, but it will involve more trouble with altering blinds than a north light. 2. About 25 feet long, by 12 feet wide, with 6 or 7 feet at eaves, and about 12 or 13 feet at ridge, will give capital proportions.

G. WILLIS.—Thanks. The subject is very interesting. If possible it will go in.

**A LITTLE PHOTO.**—Thanks. We fear too late for the YEAR-BOOK, but suitable for NEWS.

Several Correspondents in our next.
